Navy was functionally equal to that of the next two largest navies combined, and by 1900 Britain’s merchant fleet accounted for more than half the world’s shipping. The rapid growth of industrial capitalism in Europe and North America helped ensure the colonial aspirations of nations with long histories of overseas commerce like France and the Netherlands, and gave rise to new maritime powers such as the United States, Germany, Japan, and to a lesser extent Russia. The need for coaling stations contributed to the burst of European colonialism at the end of the nineteenth century. The cost of fuel (a new element in shipping costs) led to the construction of the Suez and Panama Canals, among others, and dramatic redirections of ocean commerce. Almost overnight, age-old harbors astride sailing ship routes became backwaters while others such as Singapore, on more direct routes favored by steamers, became major trading hubs.

Maritime rivalry was among the factors that led to the outbreak of World War I, and at the start of the twentieth century citizens in maritime countries took a keen interest in both their navies and their merchant fleets, especially North Atlantic passenger ships. The United States merchant marine

emerged from World War I as a major maritime power, second only to Britain. Thanks to an aggressive shipbuilding program in World War II, the U.S. merchant marine and navy were the world's largest by 1946.

Since 1950, the world's merchant fleet has grown enormously, nearly threefold in the numbers of ships and more than fivefold in total tonnage. At the same time, industry consolidation and huge gains in efficiency due to containerization and computerization since 1960 have reduced the numbers of people employed in maritime industries and forced port facilities away from traditional urban centers such as London and New York. This transition has gone all but unnoticed in the West because in the last century European and American ship operators began transferring their ships to "flags of convenience"—foreign registries with more lax labor, safety, and environmental standards. In Asian countries such as Japan, South Korea, and China, however, merchant shipping and shipbuilding is an integral part of the national economy, a fact that suggests an imminent reorientation in the balance of world power.

History, Oral

Oral history is a field of study concerned with obtaining, interpreting, and preserving historical information from verbal accounts. Eyewitnesses, or at least contemporaries to an event or period of time, can provide historians with important primary source materials, often from several points of view.

Oral history focuses on eliciting information (oral accounts) from people who actually experienced or witnessed historical events. It differs somewhat from the fields of folklore and ethnography (cultural studies), which also collect verbal information from living persons. All of these fields of study rely heavily on interviews, but they pursue different goals.

In general the folklorist seeks to uncover folk traditions known throughout a group, and the ethnographer seeks to unravel the cultural patterns and organizational structure of a group. Both the folklorist and the ethnographer attempt to interview a representative sample of people to uncover general cultural patterns, although many ethnographers are also fond of collecting biographies that embed a great deal of historical context. The folklorist and ethnographer therefore focus on reconstructing oral traditions. Oral traditions are verbal accounts of events from the more distant past that have been handed down over generations and are shared by a group of people. Oral traditions tend to become modified during long time periods, often serving to identify and legitimize a group. As one moves further and further into the past, history often fuses with legends and myths in oral tradition and folkloric accounts. Nonetheless, the boundaries dividing these fields of study are often blurry because

cultural traditions often embed intriguing information about a group's actual past, and contemporary oral history accounts frequently reveal insights into a people's culture.

Early Uses of Oral History Accounts

The incorporation of oral accounts into written histories is undoubtedly as old as history itself. Indeed, oral accounts would have predated the invention of writing as the primary means by which events and ideals of the past were captured for a group's posterity. Oral transmission has also been the usual manner in which histories and traditions have been passed from generation to generation in nonliterate societies worldwide. Among the earliest historians to explicitly rely on oral accounts was the ancient Greek historian Thucydides, who interviewed participants in the Peloponnesian Wars (460–404 BCE). Other examples abound throughout history. For instance, Franciscan friars in sixteenth-century New Spain (Mexico) relied on "the memories of the old men" to record the histories and customs of the indigenous people in their native language (Dibble and Anderson 1982, 10), and the French writer Voltaire (1694–1778) questioned lords and servants alike in preparing his history of the French kings.

Oral History: Methods and Goals

As a systematic field of study, oral history is relatively young. In the United States formal interest in oral history dates from 1938 with a suggestion by the U.S. historian Allan Nevins to establish an organization to collect oral as well as written accounts of significant events from people who had participated

The record—history—exists only in the media, and the people who make the media, make history. • James Monaco (twentieth century)

Pierre Bonirote, *A Neapolitan Story-Teller* (1840). Oil on canvas. Folklorists and ethnographers study oral histories handed down from generation to generation and eventually incorporated into written history.

in those events. The idea persisted and developed into the formation of the Oral History Association in 1966. Oral history enterprises have gained popularity in Latin America since the 1960s and in Europe since the 1970s and 1980s.

Oral historians emphasize the collection of verbal information through interviews. Other oral sources, such as scripted performances and the spontaneous recording of unrehearsed events, may embed historical information but are usually not used as major sources in a deliberately designed oral history study. The oral historian, in collecting oral accounts, has a particular research question in mind and a set of questions to elicit meaningful information about that question.

By necessity oral history focuses on the most recent generations whose memories can be tapped for their personal experiences and involvement in the historical events or moments of interest to the historian. The field has evolved from its initial interest in prominent people to an interest in everyday witnesses and participants, with ethnic and gender diversity of particular recent importance. Sophisticated digital technologies of the twenty-first century enable oral historians to accurately record interviews orally and visually and to efficiently store, preserve, and access the interviews.

Limitations, Issues, and Significance

Like historians relying on written accounts, oral historians recognize the imperfection of their data sources: memories falter, people idealize past experiences, and narratives can be selective, biased, or even fabricated. Every person sees an event from his or her unique perspective, and this perspective involves not only personality traits but also cultural background. So, for instance, Sioux oral accounts of the Battle of the Little Bighorn, on 25 June 1876, vary wildly. This variation probably derives not from faulty or selective memories, but rather from the style of Sioux military tactics that favored individual exploits over coordinated action, preventing any one warrior from gaining an overall picture of the battle. Problems in oral history can also arise from the interview experience itself: interviewers' very questions and manner can channel narrators' accounts, and, on the other hand, narrators may tailor their accounts to satisfy their perceptions of interviewers' requests. Historians are well aware that the themes driving the historical enterprise itself reflect changing political and social climates.

Like any field, oral history is not without its issues. One such issue revolves around the fundamental

mission of the field. Should it provide a record for future generations, or should projects be aimed at more immediate interpretations of recent history? Other issues reflect social changes. Should oral history serve as a means through which voices of disenfranchised persons can be heard? Additional issues concern methodologies. Should the original tapes or their transcripts be considered the primary sources? Should the people interviewed be asked or allowed to edit transcripts of their interviews? Philosophical issues mirror general trends in other social science fields, particularly a consideration of the impact of the interviewer on the interview itself and on the quality of the data collected.

Historical enterprises benefit from reliance on as wide an array of complementary primary sources as possible. Oral history adds a unique dimension to the font of primary source material. Recent research pursues a wide range of topics and gathers oral accounts from a wide spectrum of people. Oral history also has practical applications in land use claims, historic preservation, governmental and business history, and cultural impact studies.

History, Social

Historical narratives are commonly populated by the activities of states, intellectuals, and military leaders. Social historians argue that “good” histories must pay attention to ordinary people outside the realm of power; they must explore human activity and experience—such as work and leisure, emotions and the senses, or poverty and oppression.

The term *social history* can have several related definitions. The basic definition involves the exploration of the history and the historical role of groups who are outside the mainstream of power: working classes and peasants, slaves, women, the young—the list can be considerable, but the purpose is consistent. Social historians argue that these groups have a serious history, stretching from early in the historical record, and that this history powerfully shapes the activities of states, intellectuals, military leaders—the greats who more commonly populate the historical narrative. Social historians are also interested in exploring the histories of a wide range of human activities, contending that these, too, have a serious past that helps explain how human beings function at various points in earlier times and indeed in the present. These activities and experiences can include leisure, work, emotions, the senses, crime, family relationships—the list is essentially as long as our capacity to define aspects of the human condition that change over time.

Some social historians have argued that their approach involves a basic orientation to the whole of human history; others are content with a substantial reshuffling of their discipline’s standard list of topics.

Good histories have always included some social history—some attention to ordinary people and some awareness that human life consists of activities that affect each other, within which politics, for example, has a place but not a monopoly on attention. Formal social history, however, began to be defined in France during the 1930s but was not picked up in the English-speaking world until the late 1950s and 1960s, when many important works were published. Since its inception as a clear subfield of history more generally, social history has evolved. Initial efforts concentrated strongly on topics such as social protest, class structure, and mobility, with great interest in quantitative research and links with sociology. By the 1980s interests were shifting toward more qualitative efforts—sometimes called the “cultural turn”—and alliances with anthropology. Currently, as the cultural turn recedes a bit, scholars are discussing new directions and revivals of older emphases.

Social history and world history have a productive but sometimes uncomfortable, and still incomplete, relationship. Social history was focused and active at least a decade before the rise of serious modern interest in world history, and the separate beginnings inevitably raise issues of coordination. Furthermore, world history was often defined particularly in terms of the doings of great people—kings, general, and philosophers. Some partisans even argued that, because the lives of ordinary people are rather similar across societal lines, with shared poverty and oppression, they do not warrant much world historical focus, at least until modern developments brought the masses more prominently into the picture. This is an outdated argument, which no world historian would now embrace, but it did color the relationship between social

A drawing of six lamps and/or vessels unearthed by archaeologists in Jerusalem in the nineteenth century. Social historians often examine artifacts that illuminate aspects of ordinary peoples' daily lives.

history and world history for some time. For its part social history was often conceived of in terms of great place specificity. Several of the path-breaking U.S. entries into the definition of what was long called the “new” social history centered only on New England. French studies often focused on individual regions because of their particular geography and traditions. Other social historians used nations as units because of the social impact of political systems and national cultures. Source materials also dictated this rather narrow geographical impulse. Because they explore unfamiliar aspects of history, often involving groups who left little explicit documentation, social historians have frequently been tied to regional or national data sets, which are not always easy to access even on

this level. Finally, social historians during the 1980s began to pay increasing attention to cultural factors, beliefs, and forms of expression and discourse—with the “cultural turn.” As with cultural anthropology, to which the cultural approach was closely related, this attention usually encouraged social historians to take reasonably small areas as their essential purview. Thinking on a global scale was difficult.

Subjected Peoples

Yet social history has obvious bearing on world history and vice versa. Both disciplines typically deal extensively with peoples subjected to the control of others. In fact, scholars usually conceive of African history in social-historical terms, as it has surged during the past three decades—with attention to activities of peasants and workers and to popular resistance to and collaboration with outside authorities—as an alternative to older approaches that privileged colonial governments and discounted African history outside their purview. The insights from women’s history, as a branch of social history, concerning not only women themselves but also larger social frameworks, have been irresistible to world historians, and projects designed to incorporate women’s history into world history have been endemic (belonging to a particular people or country), if not yet fully conclusive, for two decades. Finally, social history itself has reached a new point of self-definition early in the twenty-first century, and appeals to reconsider geography are growing, suggesting more intensive linkage in the future.

Social history and world history remain somewhat separate. Many topics of social history, particularly the exploration of behaviors well outside the realm of politics and formal intellectual life, have yet to find a world historical application. Often, in fact, scholars have explored these revealing topics mainly in a Western context, and the topics lack as yet sufficient breadth even for significant comparative statements.

Nevertheless the connections are impressive, and they will surely expand as scholars in both disciplines interact more closely. Growing interest in the development of global contacts, as a basic concern of world

history, inevitably involves social issues: for example, in the impact of global trade or production systems on the organization of work and on social inequality. Growing interest in food habits as a social history topic readily embraces the importance of global interchange.

Even in social history's early years, a number of larger statements suggested important linkage with world history. One of the deans of French social history, Fernand Braudel, wrote persuasively of some common social structures around the Mediterranean, providing a shared framework for daily lives and ordinary people despite apparent national and religious barriers. Research of this sort, aimed at defining regions not according to religion or political systems, but rather in terms of agricultural patterns, village types, and popular cultures, could serve as a vital component of world history if the approach expanded to additional regions. Some historians and anthropologists dealing with family structures launched a somewhat similar effort to define basic family types—around household size, kinships systems, and the like—on a global basis, again often combining regions held distinct in most accounts of specific civilizations or separating regions within a presumed single civilization.

Without assuming that common people are everywhere alike, scholars realized by the 1980s that social historical findings in one society might have applicability in others. A seminal work in Western social history, E. P. Thompson's *Making of the English Working Class*, explored the value systems involved in labor protest as the Industrial Revolution took shape. A key element was what Thompson called the "moral economy," a set of expectations about work loads, treatment by employers, skill levels and training, and other job-related issues, that artisans had developed before the advent of modern, machine-based factory industry. New conditions, including novel pressures on work time and pace, violated the moral economy, which in turn both motivated recurrent protest and shaped protest goals. This moral economy turned out to be highly relevant to protests by other traditional workers, peasants as well as craftspeople, against the

advent of more capitalistic economic arrangements, including those imported under the framework of an increasingly global economy during the nineteenth century. James Scott was instrumental in showing the relevance of the moral economy in protest movements in south and southeastern Asia; following his lead other scholars applied it also to the history of Latin America. Here, then, was another huge potential in linking social history and world history: the applicability of significant reactions first studied in one area to other areas despite substantial differences in prior economic and cultural structures. In this case also, as with the early efforts at a social history-based regionalization, great opportunities exist for further work based on common human responses to roughly comparable challenges.

Comparative Applications and Chronological Patterns

As world history has gained ground, two other applications provide the most common linkages with social history. The first application is comparative. Comparisons of social structures or social experiences constitute an obvious way to utilize one of the standard world history approaches, with its emphasis on individual societies or civilizations analytically enhanced by discussing differences and similarities while also acknowledging the standard social history preference for geographically specific research.

Relying on work by area specialists, many world historians thus compare basic social systems in the classical period (c. 1000 BCE–500 CE) and after, noting the similarities, but more obviously the differences, among India's caste system, the slave-based system common in the Mediterranean, and the social system in China as it was (partially) shaped by Confucian values. Scholars have devoted more intensive analysis to slave systems themselves, probably the best-developed comparative category in social and world history. Comparison between ancient Mediterranean and later Middle Eastern slavery and its more recent U.S. counterpart highlights the greater range of occupations, and often the higher political status,

of the earlier systems, although connections existed between Roman and U.S. slave laws. Comparisons within the Americas have emphasized the greater physical brutality and higher mortality rates of the Latin American and Caribbean systems, compared to that of North America, despite the greater racism that surrounded the institution in the United States. Recent comparative research has also extended to nineteenth-century processes of emancipation. Fruitful comparison has, finally, applied to Russian serfdom and South African slavery and race relations, along with U.S. examples.

Other major social history topics are just beginning to find comparative voice. Gender comparisons remain tentative, although scholars have made interesting analyses of Christian and Islamic impacts on women in the postclassical period (500–1450). Scholars have devoted considerable attention also to the less-unequal gender systems of a few nomadic peoples such as the Mongols, compared to those in civilizations. Comparisons of feminisms have mainly stayed within a North American–European orbit (including Russia). However, research on women in Asia and Africa inevitably invokes the more familiar Western historical experience, at least for comparative suggestions. The same applies to histories of the urban working class and to labor movements and also to the growing field of the history of disabilities. Researchers also make rich global comparisons of city types and of migration patterns. With all this, comparative opportunities remain considerable, particularly for those aspects of social history that involve the wider range of human experience, such as the emotions or the senses. Even the conditions of the elderly have drawn more comparative treatment from anthropologists than from historians, who continue to treat the history of old age mainly within a Western context.

The second widespread application of social history to world history involves efforts to develop chronological models of social change that will apply to many societies in a given time period or across several periods. Some of these models explore the results of intersocietal contacts or the impacts of global forces such as trade—the two other main approaches to world history besides comparison.

Before the early modern period, that is, before the sixteenth century, patterns are not easy to discern. Because of the considerable separation among major societies, regional developments often seem distinctive beyond general similarities such as patriarchal family structures. Contacts can be explored, for example, the Chinese adaptations of Buddhism in light of Confucian beliefs about women and family hierarchy. Chinese influence on Japan during the postclassical period worsened women's status, but not to Chinese levels, while ironically providing some elite Japanese women opportunities to innovate in Japanese cultural forms (left to them because Chinese forms were more prestigious) or Buddhism. Islam's limited influence on gender relations in sub-Saharan Africa was often noted by travelers such as the Arab traveler and author Ibn Battutah.

Some scholars, seeking more general patterns, have hypothesized a trend for the status of women to deteriorate in agricultural civilizations through time. The argument is as follows: more effective political power, as governments become more sophisticated, reduces women's informal voice. Growing prosperity provides an economic margin for elite men to treat upper-class women more ornamentally. A more cultivated aristocracy, turning from war, contributes to such ornamentation as well (women often gain functions when men are away at war). Patterns of deterioration can be traced in Tang China (618–907 CE), postclassical India, and the later Islamic Middle East. However, many exceptions exist, with periods of greater women's assertion in business or intellectual life, so the model remains tentative at best.

Global Forces for Social Change

Generalizations become firmer when global forces can be more clearly identified. Significant social history was built into the world economy theory, applied from the early modern period onward. According to the theory's formulators, a society's position in the world economy (assuming significant involvement) determined a characteristic labor system—from the coercive labor of peripheral societies (Latin America, Poland) to sharecropping

It should be known that history is a discipline that has a great number of approaches. • **Ibn Khaldun (1332–1406)**

in semiperipheral societies to low-paid wage labor in core economies. The theory has often been criticized, but it continues to deserve attention for its capacity to correlate social and economic change through time on a global basis. Correlations muddy by the later nineteenth century, with the abolition of serfdom and slavery, but a strong relationship between position in the capitalist global economy and working conditions continues to hold. Current discussions about the impact of globalization on economic inequality derive directly from earlier world economy patterns and issues.

World economy theory is not the only applicable model for global, or at least extensive, social change. The Columbian Exchange between the Americas and Afro-Eurasia demonstrates the important effect of early modern biological interactions (foods, animals, diseases, conquerors, and slaves) on population levels in the Americas, Africa, Asia, and Europe. Recent research has devoted greater attention to the impact of colonialism on gender relations, through a combination of economic shifts, including women's loss of manufacturing jobs and cultural and legal influences.

Additional patterns of global social change during the nineteenth and twentieth centuries—beyond the acceleration of the world economy and, for a considerable time, imperialism—are somewhat less well defined. Attention to the dynamic of modern revolutions has always maintained a social component, involving attacks on the ruling class and discussions of the mix of social groups carrying these attacks forward along with a revolutionary political agenda. Some scholars during the 1980s disputed the social-historical basis of the French Revolution of 1789, through greater emphasis on ideology, but it is being restored in modified form, with implications for the wider set of Atlantic revolutions through the mid-nineteenth century as well. Revolutions during the twentieth century called attention to conditions and roles of peasants, along with other revolutionary elements, from Mexico and Russia early in the century through Cuba and other Latin American risings from the 1950s to the 1970s. The impacts of revolutions, similarly, can be measured through degrees of social change, for example, in the extent to which the previously dominant landholding

class was displaced. The social bases and results of movements of national liberation are harder to define but also receive attention. Here, and to an extent with revolutions as well, involvement of women, which was often followed by subsequent constraints, adds to the social dimension of one of the twentieth century's major developments.

More broadly still, some social historians have grappled with larger processes of twentieth-century social change, associated with the decline of the traditional aristocracy (a virtually universal phenomenon wherever this class had a foothold) and the rise of a professional/managerial middle class. Comparing the precise patterns of professionalization within a larger set of trends combines the two main facets of social history on a global scale. Interpretations have applied particularly to industrial societies, headed by Japan and those in the West, but they can increasingly apply to other societies with a burgeoning middle class, such as China, India, and many parts of Latin America.

Consumerism is another phenomenon increasingly receiving attention in terms of global social change. Changes in popular culture and a blurring of traditional social boundaries—class, gender, age hierarchies—were wrapped up in modern consumerism as it fanned out from the West during the nineteenth and twentieth centuries. Systematic analysis remains sparse for a subject that long seemed too frivolous for serious historical attention. However, fascinating case studies are spreading. An examination of comic books in Mexico shows how a U.S. artifact was both taken up and modified by a neighboring culture from the 1930s onward. Current research on Islam shows the growing adoption of practices such as gift and card exchange during Ramadan, a fascinating innovation in a religious holiday traditionally devoted to abstinence. As with other global patterns, including, by the 1990s, “global history” itself, opportunities for significant generalization mix with challenges for comparative analysis.

During the past decade world historians have been attempting wider incorporation of social history topics and materials, constrained in part because of unevenness of research results concerning different

societies. More recently, social historians have committed to an active discussion of a wider geographical compass for their own work. Much remains to be done to bring the two disciplines into fruitful union, but the prospects are increasingly promising.

Hitler, Adolf

(1889–1945)

NAZI GERMAN DICTATOR

Adolf Hitler, the dictator whose name conjures the horrors of the Holocaust, channeled his youthful frustrations into extreme German nationalism and growing anti-Semitism. Hitler instituted a profound social revolution in Germany, but it was highly exclusionary. Unleashed violence against Jews in November 1938 led to their resettlement in ghettos and, in 1942, to the Nazi's "Final Solution," a euphemism for the mass murder of all Jews.

Adolf Hitler is best known as the ultimate fascist dictator. After World War I he guided his National Socialist German Workers Party, popularly known as the Nazi Party, into prominence in Germany's Weimar Republic and in 1933 imposed a one-party dictatorship that steered Germany into World War II. Antidemocratic, antiforeign, anti-intellectual, anti-Bolshevik, and anti-Semitic, he was nevertheless charismatic, led an effective economic recovery, and, with help from propaganda minister Joseph Goebbels (1897–1945), developed powerful emotional and political control over most Germans by the late 1930s. Most historians consider Hitler to have been the key person who caused World War II and the Holocaust. In consequence, his very name is associated with evil.

Adolf Hitler was born in Braunau, a provincial Austrian town near Germany, to a minor customs official of uncertain parentage. The Hitler household was not happy, and Hitler was an undisciplined schoolboy who envisaged grand goals for himself as a loosely defined artist, perhaps as architect, set designer, or music critic, but his accomplishments fell far short of reality. Reduced to vagrancy, Hitler found relief

from his frustrations in extreme German nationalism, rabble-rousing politics, and growing anti-Semitism. Only Europe's call to arms in 1914 "saved" him. He joined a Bavarian regiment, preferring to render military service to Germany. Soldiering became his first real job.

Turning Failure to Success

A rarity among 1914 volunteers, Hitler survived four years of trench warfare, winning the German Iron Cross as a lowly corporal-runner (he was not considered officer material). This decoration allowed him to campaign freely in postwar German politics. The wounded veteran Hitler returned to Munich in 1919, working undercover to assess the myriad political movements that had emerged after Germany's defeat amid revolutionary turmoil. Hitler casually entered politics by joining one of the obscure parties to which the army had assigned him for surveillance.

From its outset Germany's Weimar Republic reeled under the harsh conditions imposed by the Versailles Treaty, especially its reparations clauses. Numerous extremist political parties arose, among them Hitler's Bavarian movement, which in 1921 took the name National Socialist German Workers Party with Hitler as its spokesman. The party adapted its unwieldy name to everyday usage by shortening the word *National* to *Nazi*, and Hitler personally chose the swastika, a hooked cross that became the movement's central icon. Yet, demagoguery won Hitler his central role. Prewar passions and prejudices that had existed in embryonic form within him came to the fore. An animated and indefatigable speaker (and reader), Hitler discovered at age thirty that he could rivet people's

This broadside of political cartoons published in Mexico City in 1942 ridicules the Nazi Party, Adolf Hitler, and Generalissimo Francisco Franco of Spain.

attention, be it in a beer hall or in a salon. Recognizing the emotional power of the spoken word over the printed word, he pioneered in using new electronic media such as the microphone, radio, and film.

Hitler's formula for political success was as potent as it was lacking in subtlety. The very name that he chose for his party was indicative. The National Socialist German Workers Party was ultranationalistic ("National . . . German") but also spoke for "the little guy" ("Socialist . . . Workers"). Ergo, the Nazis were

Germans first, but they came from the same bedrock class of little people whose unrecognized talents had made their nation great, that is, they were just like Hitler. He played masterfully on the public's fears and resentments, which were numerous after Germany's defeat. Hitler's message was built on absolutes: those who oppose us are traitors; those who support us are patriots.

Armed with this self-assuring message, Hitler dominated his own party, whose unruly members were

There is a road to freedom. Its milestones are Obedience, Endeavor, Honesty, Order, Cleanliness, Sobriety, Truthfulness, Sacrifice, and love of the Fatherland. • **Adolf Hitler (1889–1945)**

compelled to recognize his charisma. Outside events also helped him to build his political base. The Weimar Republic's first blow came in 1923 when French and Belgian troops occupied the Ruhr industrial area of Germany. Industry came to a standstill, and rampant inflation impoverished the nation overnight. Opportunistically, Hitler struck at what he thought was the right moment, but his Beer Hall Putsch of 9 November 1923, ended in his arrest, trial, and a five-year jail sentence.

Phoenix-like, Hitler turned his trial into a political forum and gained national recognition. During his reduced sentence of one-year fortress arrest, he wrote his memoir-cum-political statement, *Mein Kampf* (My Struggle). In turgid prose Hitler envisaged a rejuvenated Germany that would expand into an empire comprised of pure Aryan Germans, one in which Jews, Slavs, and other unwanted peoples would be banished. Fortunately for him, few people outside his party took his statement seriously. Upon his release Hitler reasserted control over his unruly following and plotted future campaigns.

From Figurehead to Führer

As long as the Weimar Republic experienced economic stability from 1924 to 1929, aided by private U.S. loans, it could pay off its reparations. Prosperity also deadened the appeal of political extremists, Nazis included. However, the stock market crash of October 1929 struck Germany's export economy with particular severity. The nation's conservative business and political leaders could not stem massive unemployment, and the Nazis and Communists successfully gridlocked government. The crisis deepened, and gradually moderate voters drifted rightward into the ranks of the Nazis. Finally, on 30 January 1933, the conservative leaders elevated Hitler to the chancellorship of a coalition government. They assumed that they could use him as a figurehead.

Hitler proved them wrong. Once in power he undermined democracy, deliberately fostering panic after an arsonist burned the Reichstag (Parliament) building. The Nazis herded thousands of Communists

and other opponents into hastily erected concentration camps. In March 1933 Hitler forced passage of an enabling act that granted him dictatorial powers and emasculated the Weimar constitution. Weimar's last election gave the Nazis only 43.9 percent of the vote, but that plurality enabled Hitler to wield complete power. Soon he suppressed all other political parties, absorbed the trade union movement, and instituted *Gleichschaltung* (leveling), the co-opting of all political, social, and professional associations into his party apparatus. Germans were compelled to greet each other daily with the words "Heil Hitler!" and an outstretched right arm. That greeting powerfully reinforced political conformity.

Shunning orthodox economic advice, Hitler began construction of expressways and public housing, programs that he had blocked while in opposition. Quietly he also initiated massive rearmament programs. Within months the economy improved, unemployment ebbed, and Hitler's popularity soared. Renewed prosperity plus the use of terror even within his own party—as happened in June 1934 when he purged his Sturm Abteilung (Storm Troopers) in the so-called Night of the Long Knives—created a Hitler myth: Germany's all-knowing Führer (leader) was forging unity at home and rebuilding prestige abroad. Propaganda minister Goebbels powerfully reinforced Hitler's image as an infallible Führer.

Hitler instituted a profound social revolution in Germany, one that affected citizens' daily lives and attitudes, but it was highly exclusionary. Only Germans could participate because in Hitler's mind-set Jews and other foreigners were inferior to Aryans. By stages he isolated Germany's Jewish citizens, first with business boycotts and purges of the civil service in 1933, then with his Nuremberg Laws of 1935, which denied Jews citizenship or the right to marry Aryans. Ominously, a vast pogrom (massacre) on 9 November 1938 unleashed violence against Jews and led to their resettlement in ghettos. Finally, in January 1942 at the secret Wannsee Conference, members of Hitler's inner circle, including Reinhard Heydrich (1904–1942), leader of the paramilitary Schutzstaffel (Protective Echelon), settled upon their

“Final Solution,” the Nazis’ euphemism for the mass murder of all Jews. Hitler never issued written orders, but his subordinates knew his wishes and hastened to carry them out.

Master of Deceit

From the outset Hitler knew that his policies would incite fear abroad. Anticipating this, he masqueraded as a defender of peace. In retrospect his actions showed him to be a master of deceit who played on Europe’s war weariness in order to win concessions. Between 1935 and 1939 he repeatedly caught other nations, especially Britain and France, off guard. Their leaders hoped to appease him with timely compromises. Hitler scrapped the Versailles Treaty, openly rearming in 1935, remilitarizing the Rhineland a year later, annexing Austria, then the Czech Sudetenland in 1938, and finally the rest of Czechoslovakia a few months later. Simultaneously, he outspent France and Britain on rearmaments six times over, transforming Germany into a military superpower by the time he invaded Poland on 1 September 1939, beginning World War II. Opportunistically, Hitler shared his Polish conquest with the Soviet dictator Joseph Stalin (1879–1953), a diplomatic marriage of convenience that lasted scarcely twenty months.

Initially Hitler’s armies ran rampant, defeating all opponents and forcing Britain’s expeditionary forces back into their home islands. By June 1941, along with his Axis (Germany, Italy, Japan) partner, the Italian Premier Benito Mussolini (1883–1945), Hitler held sway from Norway to North Africa. However, at this time Hitler’s character flaws surfaced. His ultimate goal, *lebensraum* (living space), required that he conquer the vast eastern territories occupied by Slavic peoples in order to achieve his fantasy of a greater German *Reich* (empire) that would last a thousand years. He was also convinced that he alone could accomplish such a feat. Pessimistic about his own longevity, Hitler was determined to finalize his conquests within his lifetime.

In July 1940, after Germany’s victories in the West, Hitler ordered the preparation of Operation

Barbarossa, his plan for conquering the Soviet Union. Accordingly, 3 million soldiers attacked eastward on 22 June 1941. At first his Wehrmacht (armed forces) attained easy victories over the surprised Soviets. However, enough defenders survived over the vast expanses and deteriorating weather conditions to halt the invaders before Moscow in December 1941. Soviet reserves launched fierce counterattacks that threw the astonished Germans back. Hitler’s hopes of rapid victory proved illusory. He had embroiled his country in a lengthy war of attrition. Amazingly, Hitler compounded his error by declaring war on the United States four days after the Japanese attack on Pearl Harbor, turning the conflict into a world war.

Total war revealed severe weaknesses in Hitler’s governmental structure. Ever since his youth Hitler had held social Darwinist notions of life as an eternal struggle. The title of his book, *Mein Kampf*, implied as much. These notions manifested themselves in the way that Hitler created agencies with overlapping authority in order to foster tension among competing officials. Ultimately all threads led back to him so that he could control his minions amid their institutional infighting. As a result, Germany’s administration and armed forces suffered from duplications of effort and muddled lines of authority. Hitler’s personality was unsuited to the administrative drudgery that might have blunted such chaos. In consequence, strategic decisions were delayed or never resolved. Scientists and technicians received contradictory orders for weapons development and other war-related activities (many of Germany’s best scientists were in exile). Industrialists never geared up properly for a long war; thus, production remained static until too late. Hitler’s disdain for women precluded their effective mobilization for the war effort. Occupied European nations discovered that their conquerors behaved like thugs and stole production, services, capital, artworks, and people in the form of forced labor. Genuine cooperation ceased, and the occupiers acquired only a fraction of the support they needed. Hitler’s hatred of “inferior” peoples such as Jews and Slavs turned the war in the East into a racial war; thus, the captive populations, many of whom

despised Communism and its cruel master, Joseph Stalin, never coalesced as a labor pool for Germany.

Ultimately Hitler's role as commander-in-chief defeated him. After the victories of 1939–1941 he convinced himself that he was military genius. In his youth his intuition had told him that he was a great artist. Now, in wartime, his intuition convinced him that he was a great captain on the order of King Alexander of Macedon, the Carthaginian general Hannibal, or the French emperor Napoleon. In reality he was an amateur. Hitler alone ordered the invasion of the Soviet Union without adequate intelligence. He bobbled his army groups in the opening campaign of 1941 while issuing his cruel Commissar Order for the indiscriminate killing of Soviet leaders (and by implication the entire Russian intelligentsia). Most fateful was his decision a year later to steer his soldiers into the Battle of Stalingrad, where an entire German army was annihilated. Neither Hitler, nor his once-adoring public, nor his armies recovered from that blow as the Allies (France, England, China, Russia, and the United States) closed in from east and west. For that eventuality, Hitler and his generals had no solution despite the smoke and mirrors that he and his propaganda minister threw up about exotic new "vengeance" weapons, an "impenetrable" Atlantic Wall, or the German people's "fanatical" will to resist.

Too late small numbers of Germans concluded that Hitler was leading their nation over the abyss, and on 20 July 1944, they nearly assassinated him. Nevertheless, the attempt failed, and Hitler remained in control until, surrounded by Soviet forces in Berlin, he committed suicide on 30 April 1945. Even as his ultimate fate approached, he refused to accept blame or express remorse for any of his decisions. In February 1945 he had issued his notorious "Nero" order calling for the destruction of Germany's basic infrastructure. Had his followers carried out his scorched earth policy, millions of Germans would have died from malnourishment, exposure, and disease. Fortunately,

recipients of his order, such as his chief technocrat, Albert Speer (1899–1979), balked. The pity is that they had not disobeyed him sooner.

Before Hitler committed suicide, he prepared his last will and testament. Far from an apology, it was yet another mumbling diatribe against the Jews and an indictment of his own people for failing him in executing his hate-filled schemes. His will became part of the historical record and helps explain why the name "Hitler" is synonymous with "evil."

HIV/AIDS

Epidemiologists isolated the human immunodeficiency virus (HIV) that causes acquired immune deficiency syndrome (AIDS) in 1984. Cultural attitudes about this epidemic, sexually transmitted disease and the populations it affects—homosexual men, male and female sex workers, drug addicts, and citizens of underdeveloped countries—subdued the initial response to the crisis. AIDS will continue to destabilize economically and politically vulnerable communities and countries until an HIV vaccine is developed.

The appearance in Western medical literature in 1981 of a strange and inexplicable cluster of clinical manifestations—unusual opportunistic infections, cancers, and metabolic or neurological disorders—marked the emergence of what would become a global pandemic known as acquired immune deficiency syndrome, or AIDS. Efforts to find a cure for AIDS are in full swing at the beginning of the twenty-first century, but initial responses to the onset of the crisis were sluggish. Those responses have been determined by cultural attitudes toward disease (both epidemic and sexually transmitted) and by the socioeconomic disadvantages of the populations most closely associated with AIDS (homosexual males, male and female sex workers, drug users, and citizens of underdeveloped countries).

History of the Epidemic

While epidemiologists who study the origins of disease rely in part on documentation such as medical and autopsy reports, and material evidence such as

serum and tissue samples, tracing the history of a disease ultimately requires a certain amount of speculation. In the case of the virus that causes AIDS (human immunodeficiency virus or HIV, first isolated in 1984), a preponderance of evidence suggests it originated among monkeys in western Africa, moving from simian to human populations perhaps as early as the mid-twentieth century. From there it was rapidly transmitted from human to human by means of infected bodily fluids such as blood, semen, or vaginal secretions.

Increased travel between rural and urban Africa in the postcolonial period, as well as travel between Africa and Europe or the United States, helped spread the virus to the developed world. A number of aspects of modern society—including population mobility, relaxed sexual mores, intravenous drug use, and medical innovations like blood transfusion and organ transplantation—have facilitated the spread of HIV, which lives in the body for an extended period before manifesting itself in opportunistic infections.

In the late 1970s, the first documented cases of the medical syndrome occurred among gay men in urban centers of the United States with large gay communities, chiefly Los Angeles, San Francisco, and New York. Official recognition of what would eventually be called AIDS was published by the Centers for Disease Control in June 1981. Physicians in France and England took note of these cases, which were comparable to their own clinical observations during the same period.

A syndrome rather than a disease, AIDS, unlike most bacteriological or viral infections, does not manifest itself in a single symptom or even a small cluster of symptoms. Instead, HIV attacks the cells

The CD *Jikilele* was recorded in 2001 by the Generics, a choir comprised of individuals working with the Treatment Action Campaign (TAC). TAC advocates for greater access to treatment for all South Africans.

responsible for the body's immunological defenses, making the body vulnerable to a wide range of common but normally unthreatening bacteriological and viral agents. Thus, in the early years of the epidemic, a clinical diagnosis occurred only after the appearance of secondary infections, making it difficult for physicians initially to recognize a pattern or even identify the causal agent and its presence in patients. Several years elapsed before a viral cause and a clinical test for antibodies were determined. Slow to cause the immunodeficiency that signaled its presence, HIV had ample opportunity to be spread by those who did not know they were infected. Unlike the causes of past epidemics such as plague, smallpox, or influenza, HIV could survive unnoticed in the infected for months or even years.

Historically, different cultures have responded to epidemic disease in remarkably similar ways. In the ancient and modern worlds, plagues have often been viewed as divine punishment for breaking taboos or committing sins. (For example, both Homer's *Iliad* and Sophocles's *Oedipus the King* begin with such plague punishments.) Because AIDS was first documented among intravenous drug users, sex workers, and men who were having sex with men, these

already stigmatized groups were regarded by many as undeserving of medical treatment, and the culturally or legally proscribed activities that served as modes of transmission were frequently left out of public discussion. Even today, more than twenty years into the epidemic, much of the debate about HIV-prevention training remains mired in conflicts over cultural and religious values rather than discussions about effective public health practices.

In addition, during an epidemic the unaffected can conclude either that only the marginalized group is vulnerable (in which case, no further action is required) or that everyone is vulnerable (so the marginalized group needs to be expelled or contained and regulated). Throughout the first two decades of the AIDS epidemic, governments and communities made both assumptions, in violation of standard public health practices. Heterosexuals in industrialized nations assumed AIDS was a homosexual problem. African-American clergy and leaders assumed it was a white problem. African leaders assumed it was a problem of former French, English, or Belgian colonizers and American hegemonic capitalists. Communist leaders in the People's Republic of China and the Soviet Union assumed it was a decadent bourgeois problem. The result of this blindness was a lack of AIDS-prevention education and health monitoring worldwide, allowing infection rates to soar.

Recent Trends and Future Prospects

The end of the Cold War and the rise of a more tightly knit global economy have in many ways exacerbated the AIDS problem. Within the old Soviet bloc, the end of communism resulted in economic dislocation and hardship, which in turn increased the rates of poverty, intravenous drug use, and prostitution while reducing the capacity of socialized medicine to respond to the epidemic. Expanded trade in Africa and Asia similarly facilitated HIV transmission among marginalized or migratory workers. The rise of the Internet and the attendant proliferation of online pornography have resulted in new types of sex work as

AIDS: 1 in 61, a bilingual poster by Gran Fury (artists' collective).

a form of economic subsistence. In addition, airline deregulation has encouraged Western sexual tourism in developing nations.

Furthermore, the development in recent years of effective pharmaceutical treatments to manage HIV infection has brought with it unintended consequences. In Western industrialized nations where such medications are available, some people have become lax about employing AIDS-prevention measures, and infection rates in some populations have risen. In developing nations where AIDS medications are prohibitively expensive, governments and non-governmental organizations have had to lobby for reduced drug costs.

A rationalist Western scientific worldview will continue to be confronted by a variety of local beliefs and values. To Western medicine, AIDS is simply caused by a virus (HIV) that is commonly transmitted through unprotected sex; the prevention of HIV transmission, therefore, is simply a matter of preventing HIV infection (through sexual abstinence, through sexual fidelity to one partner, or through use of condoms or "safer sex" practices). But sexual

behavior is notoriously immune to rational choice. Furthermore, the power to make and enforce decisions about safer sex is often asymmetrical in many cultures, with males having greater power over females or johns having greater power over prostitutes. Misinformation and falsehoods about HIV and AIDS are prevalent in many communities (such as the belief that one can tell by a person's appearance if they are HIV infected or that an HIV-infected man can be cured by having sex with a virgin). Even HIV/AIDS denialism (rejecting HIV as the cause of AIDS) is not simply the peculiar aberration of a few individuals but can influence public policy, as in the case of former South African president Thabo Mbeki's opposition of antiretroviral medications in that country.

AIDS will continue to destabilize economically and politically vulnerable communities and countries until an HIV vaccine is developed. Research into a cure for AIDS continues apace; but until researchers develop an effective vaccine, AIDS-prevention education and a commitment by Western nations to provide funds for medical treatment will remain the primary means of limiting this epidemic.

Ho Chi Minh

(1890–1969)

VIETNAMESE NATIONALIST LEADER

Ho Chi Minh was the most prominent leader of the Vietnamese nationalist movements against French colonialism in the 1940s and 1950s. He epitomized the will of colonized peoples to obtain independence from Western imperialism, but also embodied the paradoxical convergence of two apparently conflicting ideologies: nationalism and Marxism.

Nguyen Sinh Cung, born in the Vietnamese village of Kim Lien, in Nghe An province, assumed multiple aliases during his years as a revolutionary, but was best known as Ho Chi Minh, which means “He Who Enlightens.” Ho Chi Minh grew up in a poor family of Confucian scholars. His father, despite being a scholar-official, preferred to remain in the village to teach rather than serve an imperial court he considered corrupt. At the time, Vietnam had been broken up into three fragments (Tonkin, Annam, and Cochinchina) under the colonial control of France. The Vietnamese royal court, centered at Hue, the imperial capital, and under the nominal rule of the Nguyen dynasty, answered to the French. Ho Chi Minh was thus steeped early on in an atmosphere of fervent nationalism. In 1911, after pursuing an education at the National School in Hue, Ho Chi Minh decided to travel to the West to search for ways to liberate his country, which had been colonized by the French since 1862. Ho Chi Minh’s travels were to last him thirty years, but in 1917 he alighted in Paris, a fertile ground for revolutionaries. He joined the French Socialist Party, frequented Vietnamese nationalist milieus, and published anti-colonial articles in his journal, *The Pariah*, under the alias Nguyen Ai Quoc (“Nguyen Who Loves

His Country”). World War I ended in 1918, and in 1919 came the peace conference at Versailles. Ho Chi Minh used the conference as an opportunity to present a list of reforms to the delegations present; when he was turned away, Ho Chi Minh, who had already been involved in French socialist activities, became even more deeply committed to Marxism. In 1920 he became one of the founding members of the French Communist Party, where he advocated for Vietnamese independence.

In 1923 he traveled to Moscow for further Marxist training, and from 1924 he traveled and worked as a Communist revolutionary in various parts of Asia. What drove him foremost was his mission to liberate Vietnam from French rule, at whatever cost. Jailed, tortured, sentenced to death, and surviving years of hardship, Ho Chi Minh emerged the undisputed leader of the Vietnamese Communist movement when he founded the Indochinese Communist Party (ICP) in 1930 in Hong Kong.

The French colonial government was at its weakest during the Japanese wartime occupation of Vietnam, and it was in 1941, during the occupation, that Ho Chi Minh returned to Vietnam and established the Viet Minh Front, or the League for the Independence of Vietnam. The surrender of Japan on 16 August 1945 gave the Viet Minh the opportunity to launch its nationwide August Revolution and to seize power. On 2 September 1945, in Hanoi, Ho Chi Minh, by then an emaciated, wizened man, read the Declaration of Independence, declaring the formation of the Democratic Republic of Vietnam (DRV).

The French were determined to regain their colonial possessions, but the First Indochina War (1946–1954) concluded with the French defeat at

You will kill ten of our men, and we will kill one of yours, and in the end it will be you who tire of it. • **Ho Chi Minh (1890–1969)**

Portrait of Ho Chi Minh (c. 1946). This photograph was a gift to Raymond Aubrac, the father of Ho Chi Minh's goddaughter. The French written around the photo translates: "A big kiss to my little goddaughter Babette. Your godfather, Ho."

Dien Bien Phu in May 1954. The Geneva Accords, signed in July 1954, temporarily separated the warring parties on either side of the seventeenth parallel until elections scheduled for 1956. In the north was the DRV under President Ho; in the south were the French, from which emerged the Republic of Vietnam under Ngo Dinh Diem (1901–1963). In the north was the Democratic Republic of Vietnam (DRV) under President Ho; in the south emerged the Republic of

Vietnam (RVN), inaugurated on 23 October, 1955, under Ngo Dinh Diem (1901–1963) who refused to hold the 1956 reunification elections as stipulated by the Geneva Accords. With the United States' intervention, the Second Indochina War (1960–1973) plunged Vietnam deeper into bloody and destructive conflict. The Communist forces continued the combat with the U.S.-sponsored southern regime, which the DRV considered illegitimate. Until his death on 2 September 1969, Ho Chi Minh was able to keep the DRV focused on carrying on the struggle. His stature acquired legendary proportions, and he became known as Bac Ho or "Uncle Ho" among supporters. Ho Chi Minh came to symbolize the Vietnamese determination to resist, and his name was chanted repeatedly in antiwar marches in the 1960s and 1970s in the West and in Third World countries. Ho Chi Minh was deft in steering the DRV through the shoals of Communist rivalry that pitted the Soviet Union against China during the Sino-Soviet crisis while managing to obtain vital economic, financial, and military aid from both. His final wishes were that his ashes be deposited in the three regions of Vietnam, but he was embalmed and remains in state at the Ho Chi Minh Mausoleum in Hanoi.

Holocaust

Adolf Hitler's plans for "the extermination of the Jewish race in Europe" during World War II were manifest in what became known as the Holocaust, in which some 6 million European Jews perished.

Prior to the mass slaughter of European Jews by the Nazis during World War II, commonly known as the Holocaust, German dictator Adolf Hitler made no secret of his intentions. Writing in prison in 1924, he laid out his anti-Semitic views in the book *Mein Kampf* (My Struggle), and he began to act on them after coming to power in 1933. Though great effort was ultimately devoted to concealing the murder of Jews in concentration camps, Hitler repeatedly spoke publicly about his plans, predicting in January 1939, for example, the "extermination of the Jewish race in Europe" in the event of war.

Despite Hitler's openness about his objective, few people inside or outside Germany took his words seriously. After all, Germany was regarded as one of the world's most civilized nations, and Jews were among its most prominent citizens. It therefore came as a shock when a boycott against Jewish businesses was initiated early in 1933.

Gradually, the persecution of Jews in Germany escalated, culminating in the adoption of the Nuremberg Laws in 1935. These laws excluded Jews from all public business life and denied them the right to vote or hold public office. Later, professionals such as doctors were stripped of their licenses. The Law for the Protection of German Blood and German Honor prohibited the marriage of Jews to non-Jews. Other bans prevented Jews from using the same facilities as non-Jews. In 1937, the Nazis began to confiscate

Jews' possessions. Jewish children were expelled from school, Jews were banned from cultural and sporting events, and limits were placed on what Jews could do in public.

The prohibitions were devised, implemented, and enforced by a bureaucracy devoted to the "Jewish question." Virtually every government institution contributed to the Nazi anti-Jewish policies. Among the most important were the Press and Propaganda Ministry, which fed the German people a steady stream of anti-Semitic propaganda. The result was the dehumanization of Jews to the point where ordinary citizens were willing to persecute or even murder Jews while others watched silently. While it may be an overstatement to say, as some scholars have, that Germans were predisposed to anti-Semitism, few Germans were prepared to raise any objections to Hitler's policies.

The Danger Rises

The discriminatory measures adopted in Germany did not initially pose a physical threat to the Jews. This began to change on 9–10 November 1938, when the government organized attacks by mobs that destroyed 191 synagogues and looted 7,500 shops. At least ninety-one Jews were killed in what became known as the Night of Broken Glass, or Kristallnacht.

The authorities' clear role in the attacks convinced many Jews the time had come to flee. The question, for those with the courage and the means to leave their homes, was where to go. Just four months earlier, delegates from thirty-two countries had met at Evian, France, to discuss what to do about the growing number of refugees trying to flee Europe.

Young Jewish girl in a Polish ghetto (c. 1940).

Malnutrition in ghettos was widespread, and death by starvation and disease was a daily occurrence. New York Public Library.

The United States, which had initially proposed the conference, showed so little interest in solving the problem that other countries felt no need to open their doors to fleeing Jews. In the end, the Dominican Republic was the only country that welcomed Jews.

The situation grew increasingly ominous for the Jews when more than 26,000 Jewish men were imprisoned in concentration camps at Dachau, Buchenwald, and Sachsenhausen. The first of these camps, Dachau, was established in June 1933 for non-Jewish opponents of the Nazi regime and other criminals, but Dachau, along with the others, gradually became prisons primarily for Jews.

World War II Begins

Germany's invasion of Poland on 1 September 1939 marked the unofficial start of World War II. One of the reasons Hitler said he went to war was to make room—*lebensraum*, or “living space”—for Germans. He believed that eastern Europe had to be conquered to create a vast German Empire with a greater population and new territory to supply food and raw materials.

The conquest of Poland, however, brought another 2 million Jews under German authority. These people needed to be removed to create the German living space. Toward that end, Heinrich Himmler, the head of all German police forces, created special task forces

within the elite SS, called *Einsatzgruppen*, which were charged with liquidating all political enemies of the Third Reich.

The *Einsatzgruppen* killed approximately 1.4 million Jews in actions that involved little more than lining men, women, and children up in front of ditches and machine-gunning them. Ultimately, however, the mass shooting of Polish Jews was not practical, so while the Nazis planned the creation of special camps for the efficient extermination of the Jews, they decided to isolate them in ghettos.

Ghettoization

The Polish ghettos were enclosed areas—barbed wire at Lodz, a brick wall in Warsaw and Cracow—guarded by German soldiers. The Jews tried to live as normally as possible, but conditions in the ghettos were horrible. Malnutrition was widespread and death by starvation and disease was a daily occurrence.

Each ghetto was administered by a Jewish council (*Judenrat*) composed of influential members of the Jewish community who had to decide whether to help the Nazis or risk being murdered for their refusal. While the *Judenrats* hoped to improve the plight of Jews in the ghettos, they were often forced to choose who would be deported to the death camps. Ultimately, their cooperation did not save them from

Oven in the concentration camp at Buchenwald, Germany, during World War II. Library of Congress.

suffering the same fate as the other Jews. In 1942, Hitler decided to liquidate the ghettos and, within eighteen months, had the more than 2 million Jews deported to death camps.

The Final Solution

The first people Hitler systematically began to murder were not Jews. In September 1939, he gave an order authorizing doctors to grant “the incurably ill a merciful death.” The program was based in Berlin at No. 4 Tiergartenstrasse and became known afterward as the T-4 program. Patients from hospitals all over the Reich who were considered senile, insane, or in some way “mentally defective” were marked for death. Initially people were killed by starvation, then by injections of lethal doses of sedatives, and ultimately by gas. The gas chambers, disguised as showers,

were first developed for use in the T-4 program, and corpses were cremated, as those of Jews would later be in the camps.

Hitler’s extermination campaign was already nearly three years old when Reinhard Heydrich, head of the SS Reich Security Main Office, arranged for a conference in the Berlin suburb of Wannsee on 20 January 1942. The German army had overrun most of Europe, and the Nazis recognized that it would require greater coordination among their various institutions and officials to accomplish the goal of a “final solution” to the Jewish question, namely the extermination of the 11 million Jews Hitler believed to be living in Europe.

From that point until the surrender of Germany, the Nazis followed the course laid out at Wannsee and murdered approximately 6 million Jews as well as an almost equal number of non-Jews. The killing continued unabated even when the tide of war turned against Germany. When every German was needed to fight, and when food, oil, and transportation were in short supply, resources continued to be diverted to the killing of Jews rather than to military use.

The Germans were determined to find practical ways to kill as many people as quickly as possible. They built six camps—Chelmno, Treblinka, Sobibor, Belzec, Majdanek, and Auschwitz/Birkenau—specifically for murdering Jews. In Auschwitz alone, more than a million people were murdered, mostly in gas chambers.

The Last Stop

Jews deported from their homes or ghettos were usually told they were being transferred to another area or sent to work; they had no idea what to expect when they were packed like animals into boxcars and shipped to their final destination. Before they knew what was happening, their possessions were seized and they were confronted by snarling dogs, armed soldiers, and officials barking orders at them. Those taken directly from the trains to the gas chambers did not realize they were headed to their deaths, and it did not occur to them to resist.

Two men sitting after liberation from Lager-Norhausen Death Camp, circa 14 April 1945. Library of Congress.

The numbers of bodies being buried eventually grew so large that the mass graves were overflowing. Ovens were installed in some camps to cremate the dead. After the Jews were killed, camp inmates were forced to extract gold from the teeth of the corpses, as well as confiscate money, jewelry, and anything else of value, which was then delivered to the German Reichsbank. Other personal items, such as clocks, wallets, and clothes, were cleaned and delivered to German troops. The best of the loot was reserved for SS officers.

Jews who were not immediately killed were segregated by sex, their personal possessions taken away, and their heads shaved. They were issued prison uniforms and, at Auschwitz (after 1941), had numbers tattooed on their arms. Prisoners were fed starvation rations and brutalized by guards.

Because the Germans believed Jews were inferior and essentially subhuman, they felt no hesitation about using them for cruel experiments. At Auschwitz, the Germans experimented with sterilization techniques. At other camps, the Nazis broke bones over and over again to see how many times it

could be done before the bone would no longer heal. Prisoners were exposed to extreme heat and cold to determine the maximum and minimum temperatures at which people could survive, and experiments were conducted to determine the effects of atmospheric pressure on the body.

Jews were not only murdered in concentration camps. At the entrance to camps such as Auschwitz, a sign read, *Arbeit Macht Frei*, or “Labor Wins Freedom.” Thousands of prisoners were literally worked to death. Others died working in German industrial factories owned by large companies such as IG Farben (which produced synthetic rubber and fuel) and Krupp (which produced fuses).

Survival and Resistance

It took luck and determination to survive in the camps or in hiding. People lived underground in caves for years, escaped through latrines, and hid inside monasteries, pretending to be non-Jews. Prisoners in the camps had to stay healthy enough to work, and that often required stealing or trading food and clothing. The very young and old had little chance of survival; more than a million children were murdered in the Holocaust. Women were more likely to be killed than men, because they were less able to perform hard labor and because they could not be allowed to live and produce more Jews.

Despite the overwhelming odds, lack of training and weapons, and their usually weak physical condition, Jews did engage in acts of resistance, such as joining armed partisan groups, participating in the uprising in the Warsaw ghetto, attempting to escape from Sobibor, and blowing up the crematorium at Auschwitz. Prisoners who refused to give in to the dehumanization of the camps displayed a different type of resistance, secretly organizing religious services or classes.

The Failure to Act

Many reports of what was happening to the Jews appeared in media abroad, but they were often buried

That was only the beginning—where one burns books, one will finally also burn people. • **Heinrich Heine (1797–1856)**

deep in the newspaper and written in a way that detracted from their credibility. Most people could not believe that hundreds of thousands of people could be murdered in a single place.

The U.S. government knew what was happening to the Jews in Germany throughout the 1930s and learned about the Final Solution by 1942. Roosevelt was urged to use the military to slow down or try to stop Hitler's killing machine, but defense officials rejected suggestions to bomb the concentration camps. Roosevelt believed the best way to save the Jews was to devote all the nation's resources to winning the war. Undoubtedly, the Allied victory saved Europe and millions of lives, but 6 million Jewish lives were still lost in part because U.S. officials made it difficult and sometimes impossible for Jews—except those who were famous or could help the war effort—to enter the country to escape Hitler. Late in the war, Roosevelt created the War Refugee Board, which took modest measures to rescue Jews, but it was too little too late.

Rescuers

The Holocaust was only possible because of the complicity of ordinary citizens. Besides the perpetrators and bystanders, however, thousands of people acted courageously and morally, risking their lives to save others. These "righteous persons" did everything from providing shelter to food to documents to Jews in danger. A few diplomats, such as Sweden's Raoul Wallenberg and Japan's Chiune Sugihara, helped Jews escape by giving them visas. In the case of Le Chambon, France, a whole town shielded Jews from their tormentors. Denmark was the only occupied country that actively resisted the Nazi regime's attempts to deport its citizens and saved almost its entire Jewish population.

War Crimes

Hitler and several of his top aides committed suicide at the end of the war to avoid arrest and prosecution. The twenty-two highest-ranking surviving officials were tried for war crimes at Nuremberg, Germany, and hundreds of other trials were held

for camp guards and others who committed atrocities. Low-ranking officials claimed they were "only following orders" and should not be held responsible for their actions, but the judges rejected this excuse. Both those who gave orders to commit atrocities and those who pulled the triggers were found guilty.

Many Nazis were executed for their crimes, but most had their sentences reduced or commuted. Others were never tried and escaped to countries in Latin America and elsewhere, where they lived quiet lives under assumed names. The United States actively recruited some Nazis to help in intelligence operations against the Soviet Union. A number of Nazi hunters pursued Nazis who escaped justice. The most dramatic case was that of Adolf Eichmann, one of the architects of the Final Solution, who escaped to Argentina and was found and abducted by Israeli agents who took him to Israel, where he was tried, convicted, and executed for his crimes against humanity. By the start of the twenty-first century war criminals were still being found and tried.

Homer

(NINTH?—EIGHTH? CENTURY BCE)

Two epic poems attributed to Homer, the *Iliad* and the *Odyssey*, became almost as influential for ancient Greeks as the Bible became for Christians. Homer offered an example of heroism that later generations admired and often emulated. When study of Greek and Latin literature became fashionable again in Europe during the Renaissance, Homeric heroism revived among the educated classes and affected war and politics once more.

Homer is the Greek poet credited with the composition of the epics the *Iliad* and the *Odyssey*. There is little evidence for a historical figure called Homer. The earliest written mentions of him date from the seventh century BCE, but these are not in agreement. A number of Greek cities claim Homer for their own, most of them in Ionia in Anatolia (modern Turkey). Textual and linguistic analysis suggests that Homer was from Euboea, a large island that hugs the east flank of mainland Greece opposite Ionia, and that he lived around 800 to 750 BCE.

Although the background for both epics is the Trojan War (c. thirteenth century BCE), which was fought at Ilium (Troy) in modern Turkey, the *Iliad* and *Odyssey* deal with distinct themes. The *Iliad* relates the rage of the hero Achilles who, insulted by the Greek leader Agamemnon, refuses to fight and urges his mother, Thetis, to have the gods turn the tide of battle in the Trojans' favor. His anger changes to grief when Hector kills his friend Patroclus, who is wearing Achilles's armor. Achilles returns to battle and kills Hector, threatening to defile his corpse until Hector's father, Priam, asks him to surrender the body for a proper funeral, which he does. The action

of the book takes place over a few days in the last year of the war, but Homer also recounts the origins of the conflict and much of the story of the previous nine years.

The *Odyssey* relates the return home of the Greek hero Odysseus after the war. Although it is regarded as more of a folktale in which the hero makes excursions to fantastic lands and the underworld, the geography of the *Odyssey* is apparently modeled on the experience of eighth-century Greece, which was then beginning its westward expansion. His homecoming takes ten years because of the obstacles put in his way by Poseidon, god of the sea. In addition to telling of Odysseus's wanderings and tribulations, the *Odyssey* also tells of the efforts of his son, Telemachus, to rid his house of the many suitors who have descended in hopes of marrying his mother, Penelope. In the end, father and son are reunited, they kill the suitors, and Odysseus resumes his place as lord of Ithaca.

Thanks to their exploration of human (and divine) motive, their narrative force, and the sheer beauty of the language, the *Iliad* and *Odyssey* have been regarded as cornerstones of the Western literary tradition since antiquity. More recent evaluations of Homer have established an important historical place for him. At the end of the nineteenth century, the German archaeologist Heinrich Schliemann discovered the site of ancient Troy, which is believed to have burned in about 1250 BCE. This discovery suggested that the story of the *Iliad* had a factual basis. If the stories originated in the thirteenth century BCE, they underwent a contextual metamorphosis so that by the time they were written down, apart from a few intentional archaisms, many of the poem's details reflect

Oh you vile gods, in jealousy supernal! / You hate it when we choose to lie with men.

• Homer (ninth–eighth? century BCE) as the goddess Kalypso in *The Odyssey*

“Homer delights foreign sailors during his captivity.”

the reality of eighth-century Greece, then emerging from a centuries-long dark age, not that of the more prosperous Mycenaean age.

The Homeric poems are also among the oldest—if not the oldest—works of written Greek and their transcription marks a crucial transition in the development of writing. The West Semitic alphabet upon which Greek is based has only consonants. Greek,

on the other hand, contains both consonants and vowels, which are essential for rendering the metrical rhythm of Greek poetry, and one theory holds that the scribe who first set down the Homeric epics was bilingual and forced to introduce vowels to accommodate the Greek. Homer’s use of dactylic hexameter was widely imitated in antiquity, most notably in the *Aeneid*, Virgil’s epic of the founding of Rome by the Trojan refugee Aeneas. The first half of the *Aeneid* recounts Aeneas’s voyage to Italy, on the model of the *Odyssey*, while the second half has the more martial spirit of the *Iliad*.

As important as the epics are as a foundation of the “Western” literary tradition, many of the plots and themes derive from older Near Eastern antecedents, the best known of which is the Epic of Gilgamesh. As well as being a standard reading in survey courses of Western literature, Homer’s legacy is seen in the design of James Joyce’s mock-heroic epic novel *Ulysses* (the Latin name for Odysseus), which Joyce divided into the Telemachiad, the Wanderings of Ulysses, and the *Nostos* (homecoming).

Hong Merchants

Because Chinese officials in the Qing dynasty (1644–1911/12) refused to have direct dealings with European and U.S. merchants beginning in the mid-eighteenth century, the government licensed hong merchants to serve as intermediaries at Guangzhou (Canton), the only Chinese port open to foreign trade from 1759 to 1842. Many became prominent and wealthy until Britain's 1842 victory over the Chinese in the First Opium War.

Since the early days of the Sino-Western trade in Guangzhou (Canton), China, Chinese merchants who were licensed by ruling the Qing dynasty (1644–1911/12) to trade with foreign merchants were known as hong merchants. The term came from the name of the trading guild, Cohong, established in 1720, to which they all belonged. As their number was highly restricted to about a dozen or less at any one time, and as the trade volume grew to very substantial size by around 1775, many hong merchants became some of the most prominent and wealthy merchants in China. During the early nineteenth century, the most powerful hong merchant was Houqua (d. 1843). The full extent of his wealth is not known, for besides running extensive business enterprises in China, Houqua also formed joint ventures and partnerships with Russell & Company, a U.S. firm that did business in China. He consigned specific shipments of goods to it for sale overseas without the knowledge of the Chinese State. He also invested directly in the United States, including in stocks in the transcontinental railroad. From what can be gleaned from various accounts, Houqua appears to have been worth several million

U.S. dollars, and thus may well have been the richest man in the world at that time.

Not all hong merchants were as successful. Indeed, there were many who, for a variety of reasons—highly speculative ventures, poor management, unduly heavy pressure from government officials, conspicuous consumption, simple bad luck, among others—had to declare bankruptcy. These failures became so prevalent in some years that, by 1775, the Cohong decided to establish a kind of self-insurance fund, called the Consoo Fund, to cover the debts left behind by their bankrupt members. The fund was officially recognized in 1780. Each member paid 10 percent of his previous year's profit to the fund annually. In 1789, in order to ensure that no debts would be owed to foreign merchants, the Qing authorities imposed a 3 percent levy on foreign imports that went to augment the fund.

While the main functions of the hong merchants were the buying and selling of goods for the foreign merchants that congregated at Guangzhou, the only Chinese port opened to foreign trade from 1759 to 1842, they were also charged to secure the port, collect all the port charges and papers for each arriving or departing foreign vessel, and guarantee the good behavior of individual foreign merchants. With respect to the goods they sold to foreigners, hong merchants also stood behind quality and authenticity thereof, and if goods were returned, then the hong merchants were obligated to replace them without charge. They also gave advice to supercargoes (officers on merchant ships who were in charge of the voyage's commercial concerns) and to private traders. Indeed, many life-long friendships were struck

Buying is a profound pleasure. • Simone de Beauvoir (1908–1986)

George Chinnery, *Guangzhou: The Foreign Factories* (c. 1840). Pencil and watercolor. The scene depicts thirteen factories along the riverbank that were designated for use by European and American merchants.

between Western and hong merchants, and their advice often extended from the professional to the social and personal. These friendly relationships, however, did not result in greater mutual understanding of each other's culture. Because Chinese officials refused to have direct dealings with European and U.S. merchants, hong merchants had to serve as intermediaries. Thus, in addition to handling business matters, they also took care of foreign merchants' personal needs, such as petitioning grievances, finding living quarters and household servants, and getting official permits to leave their living compounds for occasional outings in the countryside. These official functions, together with the considerable customs fees that they collected for the Imperial Household Bureau—for all taxes levied from foreign trade went directly into the emperor's private purse—gave them

access to senior officials and opportunities to receive official commendations.

Several second- or third-generation hong merchants were scholars who had passed the state examinations and were therefore treated as social equals by the local officials. As a group, they occupied a rather unique place among the Chinese merchant class. The hong merchants' exclusive trading privileges with foreigners and their position as intermediaries between foreign merchants and Chinese officials came to an end in 1842 with Great Britain's victory over China in the First Opium War. The hong merchants and their Cohong guild were disbanded, and they came to be regarded as relics of a period when the Chinese world and the Western world came together without much mutual understanding. The Chinese government did not recognize foreign trading as a private citizen's

George Chinnery, *Portrait of the First-Ranking Hong Merchant Howqua [Houqua]* (c. 1828). Oil on canvas. Collection of the Hongkong and Shanghai Banking Corporation Limited.

right. According to normative Confucian values, trading with foreigners was an element of diplomacy and therefore ought to be highly controlled and limited in scope. Nevertheless, it was not a matter of sufficient importance to involve the state directly, and hence, any communication between Chinese officials and foreign merchants was channeled through hong

merchants. On the other hand, both the Chinese and the foreign merchants worked successfully together, for they shared a similar set of values about private enterprise and profit motives. After 1842, many of the hong merchants, joined by newcomers, continued to engage in foreign trade in the form of compradors (Chinese agents in the employ of foreign firms). The Chinese worldview itself remained fractured, and it would take another generation or two before the Chinese state gave proper recognition to international trade and the critical role played by the hong merchants.

Horses

After the invention of stirrups (c. 500 CE) horsemen became especially formidable as they charged forth in battle, thrusting spears or using both hands to shoot with bows and arrows. As a result cavalry warfare became dominant throughout Eurasia for the next thousand years, and the horse remained an animal of war until plowing and pulling wagons came later.

Horses played two main roles in world history. First and foremost, they served in war, and men driving or riding horses dominated battlefields for centuries in many but not all parts of the Earth. Second, when efficiently harnessed, horses pulled plows, wagons, and coaches faster than oxen were able to, and for a short while dominated short-range overland transport until displaced by tractors and motor cars in the twentieth century, at least in the Western world. A third role survives undiminished, for horses still run races and are used to play polo and chase foxes for the amusement of elite groups, as they have done for several centuries, here and there around the globe. And, occasionally, children still ride wooden horses on merry-go-rounds.

Evolution

The evolution of horses from a small, three-toed creature called *Eohippus* that ran about in both North America and Europe some 2.5 million years ago is relatively well known. Successive species grew larger with longer legs and fewer toes until a hoofed, one-toed genus, *Equus*, evolved from

which modern horses, zebras, and donkeys all descend. Modern horses (*Equus caballus*) appeared in North America about 2.5 million years ago and spread to the Old World across a land bridge between Alaska and Asia to occupy the grasslands of Eurasia. But, for reasons unknown, the species disappeared from its North American homeland between 10,000 and 8,000 years ago, only to be reintroduced by Spaniards during their conquest of Mexico in 1519–1521. Human hunters arriving from Asia may have killed them off, but this is speculative and may not be true.

When horses arrived in Eurasia, they were highly specialized grass eaters, lived in herds (each led by a male stallion), and relied on speed to evade attackers, including human hunters. A few horses appear in the Magdalenian cave paintings of France, made between 16,000 and 13,000 years ago, and this suggests that they were among the game animals Magdalenians hunted. But domesticating fleet horses was not easy. Peoples of the western steppe in what is now the Ukraine may have succeeded in taming them about 6,000 years ago but for a long time continued to kill horses for food, just as hunters had done before. At some unknown date mares, like cows, were induced to let humans milk them, and mare's milk remained a significant resource for later generations of horse nomads across the steppes. But mare's milk was not very abundant. Cows gave more milk, and slaying male newborns to assure access to milk—however practical when applied to cattle—became costly for horse breeders when riding stallions allowed them to manage and protect their herds.

A family, with shovels and horse-drawn carts, working at the iron mines in the Bakaly hills (near Ekaterinburg, Russia) 1910. Photo by Sergei Mikhailovich Prokudin-Gorskii (1863–1944). Library of Congress.

Going to War

Riding horseback probably began almost from the start of human interaction with horses, but the earliest evidence dates only from about 3000 BCE in the form of a few clay statuettes. It took a long time before riders could safely use weapons from horseback. The first riders were probably more interested in guiding their herds to the best pastures and keeping them together than in attacking other men.

As far as we know, horses first began to play a critical part in organized warfare about 1700 BCE on grasslands adjacent to the Iranian plateau, north and east of Mesopotamia. Wheelwrights learned how to construct slender, spoked chariot wheels able to withstand the bumps and thumps caused by rolling rapidly across battlefields. A pair of galloping horses could

haul two men in a light chariot; one man held the reins and drove the horses while the other stood ready to use his bow to shoot arrows at the enemy. When such chariots were new they were very expensive, and all but irresistible in battle. Foot soldiers could not come to grips with a swarm of rapidly moving chariots, nor dodge the arrows that came so swiftly at them. The weapons charioteers used were short, resilient compound bows made of wood, bone, and sinew, and were just as difficult to construct properly as were the chariots' wheels.

Building war chariots and making compound bows required specialized skills and materials that only civilized or semicivilized societies could mobilize. Feeding horses away from the steppes was also very expensive, since grass was scarce in the earliest centers of civilization. Charioteers therefore

This Japanese woodblock print (ukiyo-e) shows the warrior Sasaki no Takatsuna on horseback at the Battle of Uji River. Created between 1772 and 1789 by Shigemasa Kitao.

remained relatively few, but success in battle assured the eventual spread from their place of origin in every direction. Western Asia was closest and most immediately affected. Charioteers from the steppes conquered Mesopotamia, Syria, and Egypt by 1687 BCE when the Hyksos came in their chariots to invade and rule over Egypt. Chariots and horses arrived as conquerors in India about 1500 BCE, and Chinese rulers acquired them some two hundred years later. Westward, chariots probably arrived in Greece from Asia Minor. A stone carving in Sweden shows that even remote European chieftains had acquired war chariots by about 1300 BCE. For the first time the whole breadth of the Eurasian continent was disturbed by the impact of horses and the styles of chariot warfare they made possible, and its peoples remained loosely but significantly in touch thereafter,

especially with respect to military and technological advances.

The Chariot's Decline

To be sure, small elite groups of charioteers did not retain power for very long. Two further changes in warfare were responsible.

One was the advent of iron armor and weapons. Iron was abundant in the Earth and became much cheaper than bronze when methods for attaining the high temperatures needed to smelt it had been perfected. Successful smelting of iron started in Cyprus and eastern Asia Minor about 1200 BCE and spread across the Old World quite rapidly. Its effect in western Asia and Greece was to enable armored infantrymen, equipped with iron helmets, shields, and spearheads, to withstand charioteers' arrows as never before; when superior in number, infantrymen were sure to be victorious in prolonged battles, since arrows were rapidly expended, and emptied quivers made charioteers wholly ineffectual.

Foot soldiers thus regained their former primacy in Greece and western Europe for the next few centuries, despite the advent of cavalry warfare among steppe nomads, which allowed single bowmen to move even more swiftly without the hindrance and cost of dragging a chariot. This, in turn, required riders to let go of the reins and rely on legs and voice to guide their galloping horses wherever they wanted them to go, while using both hands to bend and their bows and aim their arrows. Horse and man had to learn to move as one and trust each other amid all the noise and excitement of battle. This level of coordination between two such different species is almost as extraordinary as the way cows and mares allowed human hands to milk them.

Once achieved, shooting from horseback made every adult man a potential soldier among nomad peoples of the steppes. This compensated for the superior numbers of farming populations; and the superior mobility of mounted men in warfare gave nomads an enduring advantage that lasted more than 2,300 years, from the time when steppe cavalymen

This illustration shows warriors fighting from a horse-drawn chariot in a battle during the Homeric (or Heroic) age of Greek warfare. From the *Münchener Bilderbogen* series. (Munich: Braun und Schneider, 1852–1898.) New York Public Library.

participated in the overthrow of the Assyrian Empire in 612 BCE until Chinese soldiers compelled the last steppe confederacy ever to confront a civilized army to flee and submit to Russian protection in 1757 CE.

Throughout that long period the frontiers between steppe grassland and cultivated farmland witnessed a long struggle between horse nomads and settled, much larger agricultural populations living south of them. Raid and trade were alternative ways of life for both parties. Nomads welcomed grain and other supplies from the south, while civilized populations needed peace to bring in the harvests and often hired border nomads to protect them from other steppe raiders. But peace was always fragile, and raids and conquests recurrent, as each side borrowed military techniques and organization from the other whenever possible.

A New Breed

A significant shift of military balance occurred during the Parthian Empire (247 BCE to 224 CE) in Iran when Parthians developed a new breed of horse, far larger and stronger than the steppe ponies that served their nomad neighbors. Such horses, fed on alfalfa, could carry an armored rider and wear a breastplate, so

Parthian warriors became able to repel unarmored steppe raiders with comparative ease. But the big horses could not thrive on steppe grazing alone and were slower than the ponies, so a standoff set in that protected Parthian farmers from raids very effectively. News of these powerful horses reached China and in 101 CE Emperor Wudi sent an army all the way across Asia to bring some of them back. But feeding such big horses in China was so expensive that they remained rarities in Chinese armies.

Not so in Europe, for when Roman armies began to encounter big warhorses and armored archers across their eastern frontiers, the Parthian style of heavy cavalry seemed worth adopting, and by the time of Emperor Justinian (reigned 518–565) East Roman (or Byzantine) armies were mainly composed of armored bowmen who rode on big warhorses and were known as cataphracts. The fact that stirrups had by then been invented made riders far more secure on horseback.

Two centuries later King Charles Martel (reigned 714–741) granted estates to fighting men in France who became armored knights sworn to serve in his armies for a limited time each year on the same big warhorses. Unlike Parthian and Byzantine horsemen, however, these knights rode into battle carrying

A horse is a thing of beauty . . . none will tire of looking at him as long as he displays himself in his splendor. • Xenophon (c. 430–c. 354 BCE)

Leonardo da Vinci, *Study of horses* (c. 1490).
Silverpoint on prepared paper.

spears, perhaps because western Europe was still heavily forested and arrows could not pass freely through tree branches. Stirrups were essential for keeping knights safely seated when their spears engaged an enemy. Throwing a spearhead from a galloping horse allowed a knight to overwhelm anyone except another knight riding in the opposite direction, in which case one or both might be unseated or killed. These armored, human projectiles became the backbone of western European armies for the next few centuries, and knights became a powerful and often unruly privileged class in European society at large.

The Rise and Fall of Cavalry

Big horses could not find enough to eat on the open steppes, however, and steppe cavalymen benefitted from stirrups too, so nomad raiders

remained formidable wherever forests did not impede them. The apex of horse nomad ascendancy came when Chinggis (Genghis) Khan and his successors created an enormous empire (1227–1330) that extended westward from the steppes of Mongolia through Central Asia to Russia and the east coast of the Mediterranean, and also embraced the whole of China. The Mongols' extraordinary victories depended on the way Chinggis Khan broke with traditional tribal organization by borrowing Chinese patterns of military bureaucracy, forming regular units of 10, 100, 1,000 and 10,000 men commanded by officers promoted on the basis of success in battle rather than because of kinship or some other inherited status.

The Mongol armies moved with unparalleled rapidity and precision, relying almost wholly on cavalry. Yet they also enthusiastically accepted gunpowder, newly invented in China, and by spreading familiarity with its explosive power eventually paved the way for the overthrow of steppe nomad armies when handguns made arrows obsolete by about 1700. When the Mongol Empire was at its height, thousands of persons and caravans moved back and forth across the breadth of Asia, and the peoples of Eurasia began to exchange goods and ideas more intensively than before. Consequently, such influential Chinese novelties as the compass, paper making, and gunpowder all reached Europe and regions in between. Camels were the most efficient caravan animals, but horses and even donkeys played a part in long distance caravan trade as well.

In warfare, horses remained critical across most of Eurasia even after guns upset older balances by making it easy to destroy city and castle walls whenever heavy siege guns could be brought to bear upon them at close range. In civilized lands, combined forces of infantry, cavalry, and artillery became imperative. But horsemen retained much of their older prestige, riding ahead and along the flanks of advancing armies to guard against ambush or surprise, yet ready, when battle was joined, to charge en masse and deliver a decisive blow against a wavering foe and turn retreat into a route by hot pursuit.

The role of horses in war enlarged when lighter field guns were introduced, since horses pulled them and their ammunition to the scene of battle. And as roads slowly improved, horse-drawn wagons carried more and more supplies—tents, cook stoves, food, medicines, and bandages, for example—that were vital to an army's long-term efficiency. Fodder for horses was a critical necessity for every army and long restricted campaigning to summer time, when fresh herbage abounded and hay did not have to come from the rear. As recently as August 1914, delivery of hay to the British army in France occupied more shipping space than any other single item of supply.

But cavalry played no part in the trench warfare that ensued from 1914 to 1918. Railroads bore the brunt of supplying the immobilized armies, and when mobile warfare resumed in World War II internal combustion engines in tanks, trucks, and airplanes displaced horses just as they had by then been displaced in civilian life by tractors, trucks, and automobiles. Noxious exhaust gases thus terminated the military career that had been so central for horses in world history.

Pulling Plows and Wagons

Civilian roles for horses were more modest. For a long time oxen were both cheaper and easier to harness, and so pulled Europe's plows and wagons. In China and India, water buffalo were the principal animals pulling plows. Oxen and sometimes donkeys did so in western Asia where light scratch plows prevailed. But western Europeans adopted a larger, mouldboard plow after about 900 CE that needed six to eight oxen to pull it. Until padded collars resting securely against each horse's shoulder bones were invented, horses were useless for farmers since simple strap harnessing choked their windpipes when heavy pulling was required. Horses also required better fodder than oxen, and thus cost more.

In spite of that, by the seventeenth century well-fitting horse collars had been invented and horses began to pull wagons and plows in parts of western

Europe, where their superior speed allowed fewer people to plow more land and carry larger loads in less time than oxen were capable of doing. Thereafter, by slow degrees, European farmers' reliance on horses expanded, and use of ox teams diminished. Similarly, as roads were improved (mainly in the eighteenth century) coaches and wagons began to travel long distances more rapidly, and horses took over the job of pulling them. Likewise within cities, paved streets allowed horse-drawn carts and wagons to distribute commodities of every sort to desired destinations with increasing frequency. Human and horse populations both increased in number accordingly, and even when canals and then railroads cheapened long-range internal transport after the 1750s, horse-drawn vehicles continued to multiply as local deliveries increased in scale.

In North America, internal combustion engines supplanted horses very quickly after 1910 or thereabouts, though horses still hauled milk bottles through the streets of cities like Chicago until about 1940. That was exceptional, however, and only a few police horses, used for crowd control, remained on the streets after the 1940s. Tractors replaced horses on farms throughout North America and much of the rest of the developed world. Aside from their prominent use for transport and agriculture in less developed countries, today horses survive most conspicuously at sporting events—as racehorses and polo ponies, for instance, and notably in Afghanistan's famous game, Buzkashi—or as merry-go-round rides for children.

Hudson's Bay Company

The Hudson's Bay Company was a significant British trading company, leading in fur trade, exploring and developing the Canadian wilderness, and holding the biggest territory of any company in the history of the world from its foundation in 1670 till the forced sale of its landholdings in 1869. Since the land sales it has remained a significant actor in Canadian business till present times.

The Hudson's Bay Company was founded as a monopoly by a royal charter given by King Charles II (1630–1685) in concession to Prince Rupert (1619–1682), the king's cousin, and his syndicate was subscribed to by royal courtiers. Originally, and until 1970, headquarters were in London while the main area of activities was located in the Hudson's Bay area of what is now eastern Canada and northeastern United States. From its beginning the company antagonized the French, especially those of Montreal, who had already established trading interests in the Hudson's Bay area. However, temporary political affinity prevented active hostilities between the company and the French until 1689, when relations between England and France soured as William III (1650–1702) and Mary (1662–1694) ascended to the throne of England and joined the Netherlands in the League of Augsburg against France. As the political climate opened for hostilities, the conflicts of interests between French Canadians and the Hudson's Bay Company led to continued fighting for nearly a century, in which the loyalties of the Native Americans were eagerly pursued by both sides both as fighting and as trading partners.

The main products of the sparsely populated Hudson's Bay region were furs and pelts, especially highly profitable beaver pelts, which were much valued in Europe where, manufactured into felt, they were used for a range of hats, including the triangle hat that was in common use in the eighteenth century. Many of the beaver pelts were acquired through trade with the Native Americans, who through their choice of trading partners came to be allied with either the French Canadians or the Hudson's Bay Company. Originally the company offered standard European manufactured products, such as metal tools like scissors and hatchets, and vanity items in exchange for the beaver pelts traded with the natives. The exchange rate was fixed with the beaver pelt as the main currency: a "made beaver" could be precisely measured in value against European manufactured goods and the furs of other Canadian game, and tokens were even minted by the company to match the value of a pelt, with values from one-fifth to one whole beaver. In 1780, the company introduced a new product, the point blanket, which was a durable woolen blanket that won favor with European Canadians as well as Native Americans, who started to accept the blanket as one of the main goods of trade, as they found it useful both as clothing and as a standard blanket.

Contention about land arose in connection with the American Revolution, as the Hudson's Bay Company and the new states tried to claim the same territory in the border region around the Great Lakes. The dispute was settled, largely in favor of the United States, by the Treaty of Paris (1783), in which Britain acknowledged the new republic and its national borders.

Three ships of the Hudson Bay Company sailing off Greenwich, England, drawn in 1769 by John Hood, a shipwright who specialized in large pen and wash drawings of maritime scenes.

The Hudson's Bay Company was in charge of enormous landholdings, at its height estimated at about one-twelfth of the solid surface of the earth, and through its explorations into the chartered territory it provided a great contribution to the knowledge of the area. Through most of its early existence, the company was almost all male, governors as well as associated employees usually living as singles as the cold Canadian climate was considered particularly unsuitable for white women.

In 1869 the British North America Act was passed, creating Canada as a self-governing dominion of the British Empire. A condition for the formation of the new state was the sale of the chartered area and the end of the monopoly of the Hudson's Bay Company. Given no choice but to sell, the company was handsomely paid for giving up its land and rights. After the land sale and breakup of the monopoly, the company turned increasingly to retail, fur auctioning, and, after 1929, oil and gas, remaining an important factor in

Canadian business and a contributor to the allied efforts in both World War I and World War II. In 1970 a supplemental royal charter turned the company into a Canadian company, and headquarters were moved from London to Winnipeg. In the twenty-first century, the Hudson's Bay Company is Canada's biggest company in general retail and one of its five biggest employers.

Human Evolution

Disciplines involved in the study of human evolution—as a process both related to and distinct from the origins and evolution of other hominids—include anthropology, archaeology, paleontology, primatology, linguistics, and genetics. Because of the extensive time scale and the relative scarcity of data, the study of human evolution is an inexact science that requires a degree of theorizing.

One important way world historians have expanded their perspectives on humanity's past is through the integration of hominid evolution with their customary consideration of events covering the last 5,000 years. To understand hominid evolution, they have turned to the findings of paleoanthropologists, who rely primarily on fossil evidence rather than written records to reconstruct the patterns of prehistory that stretch back 5 to 7 million years, when our earliest direct ancestors in the family of hominids, an amazing variety of distinct species, notably the australopithecines, or southern apes, diverged onto their own evolutionary line. Seventy million years of primate evolution set the parameters and determined the possibilities for the origins and development of hominids. From their primate heritage, human beings have derived a unique combination of physical attributes, including large brains relative to body size, eyes capable of binocular vision, nimble hands, smaller canine teeth, and a skeleton designed for upright walking. Human evolution also rested on long-standing trends in primate behavior, including social learning and cooperation, toolmaking, and group organization.

Before discussing human evolution in more detail, however, it's important to mention the evidence used

in paleoanthropology and the types of disputes that tend to arise. Given the paucity of evidence available to paleoanthropologists, the immense gaps in existing knowledge, and the number of recent archeological finds that call into question prevailing views, world historians should not be surprised to find the experts constantly disagreeing among themselves about the variables of hominid evolution. They utilize detailed site surveys, stratigraphic observations, chronometric methods of dating, and precise forms of climatological, biomolecular, and comparative anatomical analysis to begin to interpret what they have found. They have increasingly emphasized the diversity rather than the uniformity of early hominids and the possibility that early hominids lived widely throughout sub-Saharan Africa, but have remained divided over how to distinguish one species or genus from another, and hence over the use of proper nomenclature. Such fundamental aspects of human evolution as the development of walking, speaking, and the hunting-gathering adaptation remain subjects of considerable debate.

Earliest Hominids

Despite unresolved disagreements and uncertainties, and evidence for the development of a discernibly upright posture in primate evolution, paleoanthropologists have focused on bipedal locomotion, the peculiar human capacity to walk efficiently on two legs with a fully erect posture, as the key to understanding what separated our oldest forebears from other hominoids. Indisputably, Australopithecines living in eastern and southern Africa had ape bodies adapted to permit upright balance and a striding

gait. Bipedalism represented a beneficial adaptive response to Africa's expanding open woodlands and savanna environments. Compelled to traverse the considerable distances between shrinking wooded areas as they foraged for sustenance or sought a refuge as nightfall approached, our distant forebears must have benefited from the cooling effects of upright posture, the advantages of a panoramic view, especially when striding through tall grass, and the convenience of having free hands to carry food, artifacts, or children. The occasional bipedalism that natural selection steadily reinforced as australopithecines adapted to their special niche set the stage for the subsequent evolution of every other fundamental feature that separates us from our hominoid cousins. It probably contributed to such physical modifications as progressive hair loss, improved sweat glands, and the refinement of the human hand. By indirectly encouraging tool use and heightened levels of social interaction, it may even have served as a fountainhead for the development of cultural behavior.

For several decades after the discovery of *Australopithecus afarensis* in 1974, paleoanthropologists devoted considerable attention to the fossil evidence for this relatively small, gracile species known as *Australopithecus afarensis*, which lived in East Africa between 4 and 3 million years ago. Still viewed by most investigators as the common ancestor of all subsequent hominid forms, *afarensis* possessed an almost humanlike skeleton below the neck, but a braincase only about one-third that of the modern average. In the mid-1990s, archaeologists discovered the remains of two other previously unknown hominids, *Australopithecus amanensis*, an apelike creature that apparently lived in the dense forests of East Africa at least 4 million years ago, and what researchers originally called *Australopithecus ramidus*, another East African species remarkably similar to chimpanzees.

Ramidus inhabited flat, forested regions as many as 5.8 million years ago, and apparently did walk upright, at least on occasion, although doubts about its capacity for bipedalism have led some investigators to conclude that it should be treated as a distinct genus, *Ardipithecus ramidus*. If that judgment is sustained, then only *amanensis* will be viewed as a

direct precursor of *Australopithecus africanus*, which itself completely died out 2.5 million years ago, but not before giving rise to other varieties of australopithecines as well as to the most ancient members of our genus almost 3 million years ago. One of these species, *Australopithecus africanus*, lived in southern Africa between 3 and 2.5 million years ago, giving way to a robust group that included *Australopithecus aethiopicus* and then *Australopithecus boisei* in East Africa and *Australopithecus robustus* in the far south. (Some paleoanthropologists classify *aethiopicus*, *boisei*, and *robustus* as members of the genus *Paranthropus*, which gives some impression of the degree of debate in the field.) *Robustus* died out about 1.5 million years ago, while *boisei* endured for another 500,000 years, at last succumbing to less burly creatures with larger brains relative to body size and greater dependence on tool use. The earliest forms of our genus, *Homo*, collectively known as *Homo habilis* or "handy man," were indisputably present in East Africa somewhat more than 2 million years ago, coexisting with *Australopithecus boisei* for at least a million years and with *robustus* in South Africa for a much shorter period.

Appearance of the Genus *Homo*

What paleoanthropologists have lumped together as habilines may actually have been several closely related species. At a minimum, some experts insist on differentiating *Homo rudolfensis* from *Homo habilis*. Others explain substantial variations in terms of a pronounced sexual dimorphism (that is, pronounced differences in the physical appearance of the sexes). But all agree that an abrupt species transition apparently did take place about 2.6 million years ago, and that the brain size of habilines jumped appreciably around 600,000 years later. But beyond enlarged cranial capacity, *Homo habilis* remained remarkably apelike. Paleoanthropologists have used the earliest evidence for systematic tool manufacturing—a momentous accomplishment that gave birth to the development of culture as a primary adaptive mechanism for humankind—as the means for differentiating habilines from australopithecines.

No later than 2.4 million years ago, East African hominids who may have been the immediate precursors of *Homo habilis* rather suddenly started to modify water-smoothed pebbles and rocks gathered in river beds, fashioning them into rudimentary stone artifacts suitably shaped to fit immediate needs. Soon after 1.9 million years ago, habilines had at their disposal an array of simple but clearly recognizable choppers, scrapers, burins, and hammerstones, all made in set patterns created by striking a core with a smaller stone to chip off a few sharp-edged flakes. Known as the Oldowan industry, this basic technique eventually spread throughout much of Africa and Eurasia, continuing to be practiced in isolated areas as recently as 200,000 years ago. Intentionally designed Oldowan tools enabled habilines to broaden their subsistence strategies through increased dependence on meat. While the bulk of their diet still consisted of vegetable foods, habilines probably turned with growing frequency to opportunistic scavenging of predator kills and expert tracking of small game animals. Although their hunting activities remained limited, they were beginning to define the basic contours of the gathering and hunting adaptation.

As the social organization of their bands became more complicated, the demands placed on individuals in their relationships with others may have contributed to the development of the brain. Manual dexterity, bipedalism, and tool use simultaneously showed signs of improvement, all evolving together with enhanced mental capacity. What made the hominid brain truly distinctive was its division into two asymmetrically structured hemispheres, each containing identifiable areas designed to control particular mental and behavioral functions. Among other consequences now vital to our existence, habilines may have possessed a feature of the cerebral cortex known as Broca's area, a region connected with speech in modern humans. Despite an immature larynx, which would have limited the range of sounds they uttered, habilines may have articulated a combination of vowels and consonants adequate for the exchange of some genuinely complex ideas.

Significance of *Homo Erectus*

As ever more elaborate cultural innovations augmented biological changes, the pace of hominid evolution quickened, starting with the appearance of *Homo erectus*, a species that apparently evolved from habilines in East Africa between 1.9 and 1.6 million years ago. Erectines were more humanlike in their anatomical features and behavior patterns than any of their hominid predecessors. What made them such a milestone in the biological evolution of our kind, however, was their impressive cranial capacity. The brain of *Homo erectus* was not simply bigger, but it was distinctly less symmetrical, since each part expanded at a different rate and was designed to perform specific functions.

Better control over the hand as well as the unprecedented ingenuity made possible by an increased brain-to-body ratio enabled erectines to become more sophisticated toolmakers and to create what paleoanthropologists call the Acheulian tradition. Beginning about 1.6 million years ago, they gradually learned to devise a more patterned and versatile stone artifact known as the hand axe. Erectines discovered how to remove flakes from both sides (faces) of a shaped stone core, producing two straight, sharp edges that converged at a point. Erectines made another important technological innovation when they introduced the cleaver, and they turned to other materials, such as volcanic rock and flint. No later than a million years ago they possessed a standardized tool kit containing at least eighteen types of highly effective implements, each proportioned in accordance with its intended purpose.

Nearly 1.5 million years ago, *Homo erectus* took definite steps toward the controlled use of fire, the next great cultural advance after the fashioning of stone artifacts. The domestication of fire, for which archeologists have evidence dating back 400,000 years, gave hominids their first real command over a powerful force of nature. Still unable to ignite a fire on their own initiative, they nonetheless taught themselves to collect flaming debris from volcanic eruptions and lightning strikes and actively keep it burning in small hearths. Fires provided warmth as

well as protection against dangerous animals. Erectines may have intermittently exploited fire for cooking as early as 700,000 years ago. As opportunities arose, they certainly drove game in a desired direction and opened up their hunting grounds with fire. Drawing on it in their toolmaking, they hardened green wood and occasionally bone or antler in the heat of their hearths. Along with warmth, fire provided light, permitting *Homo erectus* to lengthen the day.

Erectines learned how to turn animal skins into clothing, and at least 400,000 years ago started to build substantial, oval-shaped huts. Such attainments, taken together, underscore the extent to which they had become dependent on cultural rather than biological adaptations in comparison with their hominid predecessors. Until roughly a million years ago, the evolution of every living thing had unfolded largely in response to challenges emanating out of the natural environment. Then, uniquely with *Homo erectus*, shared understandings and norms of conduct, painstakingly learned and transmitted to the next generation, began to override behavior dictated strictly by genetic inheritance, more and more setting the context for everyday existence.

Given the size and complexity of their brains, erectines probably became more adept at sharing their thoughts through speech. Their nearly human linguistic potential enabled them to become active and

perhaps even habitual hunters. Coming together in groups to improve their chances for successful expeditions aimed at big game strengthened and multiplied the patterns of interdependence between erectines, making their social structures more complex, tight-knit, and more recognizably human than any network of relations that may have prevailed among habilines. They probably took a full million years to forge the enduring characteristics of the gathering and hunting adaptation, a lifeway at once highly flexible and extraordinarily stable.

Homo erectus was the first hominid to spread far beyond the African continent. Successive waves of a grand migration out of Africa may have started a million and a half years ago, but the first well-documented expansion into the frost-free zones of Eurasia occurred about 500,000 years later. Erectines funneled through the Near East, fanning out into southern Asia, where they encountered woodlands and savanna environments similar to those they had left behind. They simultaneously moved westward into parts of Europe without ever establishing an appreciable presence there. Reacting to mounting population pressures, tiny parties of the sole surviving hominid species dispersed by means of repeated budding—the splitting away of a small group from an existing band—in a continuous process which enabled them to reach southern China at least 800,000 years ago by way of India and Southeast Asia.

The tempo of evolutionary change again accelerated about 400,000 years ago. In what must have been a mutually supportive feedback process, erectines in Africa and Europe abruptly showed signs of perceptible cranial expansion at a time when they were mastering the deliberate ignition of fires and developing bona fide strategies for hunting large game animals. Just 200,000 years later, *Homo erectus* had virtually disappeared, having succumbed to competition from the most recent hominid species—*Homo sapiens*, or “wise man.” Isolated erectines did survive in Java until *Homo sapiens* intruded into the region between fifty and sixty thousand years ago. For world historians, the task of sorting out these issues has been complicated by experts who now argue that a hominid species called *Homo ergaster* was probably the forerunner of

modern humans, while erectines should be regarded as a branch of humankind's lineage.

Emergence of *Homo Sapiens*

Although gaps in the archaeological record have kept scholars from acquiring a clear understanding of how the emergence of anatomically modern humans actually unfolded, archaic *Homo sapiens* seem to have appeared first in north central and East Africa, but by 200,000 years ago, they had colonized much of Africa, and settled into the temperate latitudes of Eurasia. Always more populous in Africa than elsewhere, bands of archaic humans migrating out of that continent apparently displaced *Homo erectus* in one location after another, and subsequently diversified into many distinctive regional types without ever branching into more than a single species. From a cultural perspective, archaic *Homo sapiens* made few innovations beyond the sphere of stone toolmaking. About 200,000 years ago, however, an indisputable advance in stoneworking appeared in tropical Africa, and subsequently spread to Europe, most likely through cultural contacts. This more sophisticated technique, known as Levallois, relied on stone (typically flint) cores preshaped into set patterns, which allowed craftsmen to determine with reasonable consistency the dimensions of their flakes. The Levallois tool kit featured specialized scrapers and rough-hewn projectile points attached to wooden shafts among its more than fifty kinds of purposely designed implements.

The first signs of a cultural takeoff appeared with Neanderthals, or *Homo neanderthalensis*, which evolved in Europe and western Asia sometime after 250,000 years ago. Whether they constituted a distinct species or represented a subspecies of *Homo sapiens* continues to be another source of disagreement among the experts. In any case, learning to adapt to intensely cold climates, they extended the range of hominid settlement far beyond frost-free ecological zones, penetrating the great Siberian forests and unforgiving Arctic tundra. Neanderthals showed themselves to be outstanding toolmakers; they reinforced the trend toward smaller, lighter stone artifacts by improving the prepared-core techniques of the Levallois

tradition. Never exploiting the possibilities of bone, antler, or ivory, they did utilize wood in assembling what could have been the first composite tools. Striving to increase the number of specialized devices, they developed the disc-core method to yield thin flakes easily trimmed at their sharp edges. With this approach, Neanderthals maintained a tool kit of more than sixty separate types of finely crafted implements, including haftable spearheads as well as delicate little saws and borers.

By 120,000 years ago, techniques characteristic of what paleoanthropologists call the Mousterian industry had spread to Africa, probably from southern France. Exploiting nature like no hominids before them, Neanderthals pushed into habitats as diverse as the Russian steppes and the immense mountain ranges of Asia. Their propensity for wearing animal furs for clothing, erecting skin-covered tents and hut-like structures made from bones and tree branches, constructing snares with sinews, and maintaining hearths within which to start encampment fires enabled them to gather in settlements as far north as the Arctic Ocean. Armed with heavy spears and a rudimentary spoken language more complex than anything *Homo erectus* had produced, Neanderthals became magnificent big-game hunters. Still lacking the cognitive capacity essential for modern speech, they nonetheless began to bury their dead in simple but clearly self-conscious ceremonies no later than 75,000 years ago. Experts have presumed that their ritualized treatment of death reflected at least an elementary awareness of mortality, a need to think about dying, and possibly even belief in an afterlife.

Somewhat later, Neanderthals created the first known ceremonial pieces and decorative objects out of pebbles, and the teeth and bones of animals. Personal ornamentation, whether accomplished with jewelry or body paint, presumably allowed them to express a hint of individuality and offered a means of declaring whatever social status they enjoyed. They could also unequivocally assert their kinship ties, thereby regularizing interactions within and between bands. However, none of these accomplishments meant that Neanderthals could match the overall cultural levels attained by anatomically modern humans, and thus

This early study involving human evolution depicts human bones next to those of other animals. Comparative anatomy was an early focus in the field of human evolution.

make the behavioral adjustments that could have delayed, if not prevented, their extinction.

Anatomically Modern Humans

Experts who have advocated a multiregional interpretation of human origins envision distinct populations of *Homo sapiens* undergoing similar evolutionary alterations in different areas of the Eastern Hemisphere more or less simultaneously. Yet the preponderance of current archaeological, genetic, and fossil evidence seems to indicate that beings with a physiological and behavioral potential virtually indistinguishable from humans currently inhabiting Earth first evolved from African ancestors beginning about 200,000 years ago. Between 100,000 and 30,000 years ago, *Homo sapiens* appeared throughout most of the Eastern Hemisphere, gradually replacing the various populations of their archaic forebears. No later than 30,000 years ago, they had become the sole surviving hominid type, and the anatomical attributes as well as the cultural capabilities that have subsequently characterized our kind were fully formed.

The hallmark features of *Homo sapiens* were located from the neck up. They had delicately configured vertical faces with high foreheads, small brow ridges and teeth, reduced jaws, and prominent chins. Their modified vocal tracts made room for

an enlarged pharynx and for the rearrangement of vocal cords, larynx, and tongue that together permitted them to make more varied sounds—in particular vowel sounds. The ability to speak fluently was interrelated with a further enlargement and internal reorganization of the human brain, now encased in a higher, rounder skull. Amazingly, the diverse facets of our mental potential are products of the brain's structural complexity. While nearly four-fifths of the cortex remains uncommitted to particular operations, leaving substantial areas free to apply previous experience to immediate circumstances or forge links between seemingly unrelated ideas, certain parts of the brain perform highly specialized functions, the left hemisphere being organized for such tasks as sequential thinking and language, the right hemisphere for abstract and intuitive reflection.

Homo sapiens possess a unique ability to create symbols, and through symboling to infuse objects and ideas with discretionary meanings that transcend whatever may have been derived from sense experience. Symboling attained its ultimate expression in language, perhaps the most revealing outgrowth of our intelligence. Along with language came the earliest manifestations of culture based upon the symbolic expression of shared understandings. The capacity to create meaning and value and to infuse meanings and

Observe constantly that all things take place by change, and accustom thyself to consider that the nature of the Universe loves nothing so much as to change the things which are, and to make new things like them.

• Marcus Aurelius (121–180 CE)

values into objects and events made it possible for human culture to reach full expression as a marvelously flexible, quickly modified, and endlessly cumulative adaptive mechanism that has almost replaced biological evolution as the primary determinant of our long-term survival.

Upper Paleolithic Takeoff

Beginning about 40,000 years ago, anatomically modern humans were already approaching the threshold of a cultural breakthrough that would mark a profound watershed in the human experience. Armed with spoken languages that improved the transmission of information, and probably driven for the first time by population pressures, they added to their cumulative heritage at an accelerated rate. Our Upper Paleolithic ancestors thus stood on the brink of making their culture—learned systems of behavior based on their symbolizing capacities—a complete way of life. Their intensified creativity peaked at the height of the last ice age 18,000 years ago, and lost momentum roughly 11,000 years ago. In crossing this Upper Paleolithic watershed, humans fundamentally transformed their social structures, making their gathering and hunting adaptations far more elaborate, diverse, and specialized than ever before. No later than 15,000 years ago, clusters of bands in regions with unusual population densities were organizing themselves into larger tribal units that could number up to eight hundred people.

As networks of interaction became more extensive, the growing need for a formal expression of beliefs that could help them preserve values, heighten social coherence, and overcome tension and uncertainty in their lives surely contributed to the relatively swift development of human aesthetic sensibilities. Artistic creativity rapidly assumed an incredible variety of forms. Rock engravings date back more than 35,000 years, while large quantities of sophisticated ornaments made of carved wood, bone, antler, ivory, shells, and stone date back at least that far. These ornaments include personal objects such as necklaces, pendants, and bracelets as well as tools and weapons used for ceremonial or decorative purposes.

Archaeologists have unearthed artifacts more than 30,000 years old with patterned markings that may be lunar calendars and systems of mathematical notation. They have discovered remarkably beautiful cave paintings in France and Spain, sculpted figurines nearly as ancient, and the remains of musical instruments as varied as bone flutes, whistles, rattles, and drums. In addition, Upper Paleolithic peoples apparently expressed themselves through the rhythmic flow of poetry, dance, and song, although experts have little empirical evidence verifying such activities.

These arts derived their social potency from supernatural beliefs nearly as old as *Homo sapiens* themselves. Yet another manifestation of abstract thinking, human spirituality and religious responses to the world soon permeated every facet of daily existence. *Homo sapiens* discovered a means of comprehending perceived phenomena in terms of ubiquitous spirits, all instrumental in determining what happened in the world through activities almost everyone could understand. Through a holistic formulation of mythic concepts that embodied the actions of these spirits, they elaborated on what little they knew about the world from direct experience with visions that inserted humankind into a single, all-encompassing order of existence.

Like the spectacular burst of innovations in art and religion, radical advances in Upper Paleolithic tool-making beginning roughly 35,000 years ago reflected the newly enhanced symbolizing capacity of modern humans. All of a sudden craftsmen were devising a wide range of more specialized, durable, and efficient implements. Along with at least 130 identifiable devices, the tailored clothing, control of fire, and insulated shelters that anatomically modern humans developed helped them expand throughout Earth's habitable regions during the Upper Paleolithic.

Peopling of the Planet

Waves of migrations out of Africa, where populations were heaviest, began modestly around 100,000 years ago, exploded 40,000 years later, and by the start of the Holocene epoch 10,000 years ago gave to humankind a virtually global range. Pushed forward by

frequent band splitting, *Homo sapiens* soon traversed the open grasslands of a Sahara region somewhat cooler and wetter than it is today and moved into the Near Eastern corridor. A progressively arid climate then drove excess populations into the steppe lands and tundra of southern Europe and western Asia. Anatomically modern humans appeared in East Asia 70,000 years ago at the very latest, reaching the heart of what is today China perhaps 30,000 years ago, not too long after Cro-Magnons (a particular population of anatomically modern humans) had established themselves in Europe and at approximately the same time that pioneers were starting to adapt to Arctic latitudes in earnest.

By moving along the southern shores of Asia, humans reached Australia some 40,000 years ago and perhaps as much as 20,000 years earlier. Around 45,000 years ago, the sea level in Australia was probably about 200 meters lower than it is now, meaning that mainland Australia and adjacent islands would have been connected. It is reasonably widely accepted that at this time people had already arrived in the region. There is also some evidence, such as at Lake Mungo in New South Wales, that suggests Australia was home to small populations as early as around 62,000 years ago. At the least there is some mitochondrial DNA evidence that lends support to the disputed theory that the peopling of Australia took place earlier than 45,000 years ago as a single founder population that was later cutoff or isolated from much of the rest of the world.

Although experts hold various theories about the peopling of the Americas, they agree that it happened at a relatively late date, and most likely involved a land bridge across the Bering Strait, known as Beringia, which appeared and vanished as ocean levels rose and fell. Although the earliest evidence for possible human settlement in the Americas has been problematic at best, isolated bands may have reached central Alaska as many as 40,000 years ago. Archaeologists have recently verified a site of human habitation at Monte Verde, located roughly 800 kilometers south of Santiago, Chile, that was certainly occupied 12,500 years ago and may date back more than 30,000 years. What experts have concluded with confidence is that

between 14,000 and 12,000 years ago, scattered Paleo-Indian settlements with tool kits, languages, and cultural traditions resembling those common on the other side of the strait expanded throughout eastern Beringia and south of the retreating glaciers onto the Great Plains. Shortly after 12,000 years ago, the Paleo-Indian population suddenly exploded, pushing human beings to continuously occupy much of the Americas within several millennia.

Here it is worth noting a theory associated with the volcanic eruption at Lake Toba, on Sumatra (Indonesia) around 70,000 to 75,000 years ago. Probably one of the largest volcanic eruptions of the last twenty-five million years, it is thought to have plunged the Earth, already in the midst of an ice age, into an even darker and colder phase. Based on mitochondrial DNA evidence, it is thought that this cold snap might have reduced the world's human population to less than 10,000 breeding pairs, effectively creating a sort of "bottleneck" in human evolution. Nevertheless, by the end of the most recent ice age, *Homo sapiens* had established themselves as the most numerous and widely scattered mammals on the planet, a dominant species culturally equipped to manipulate the natural environment in a manner potentially beneficial to their well-being, but simultaneously disruptive of the ecosystem's sensitive balances. Although world population had probably reached 10 million in the aftermath of the Upper Paleolithic watershed, the gathering and hunting adaptation continued to prevail everywhere *Homo sapiens* resided. The attributes that now distinguish us as human beings had emerged at different stages in a prolonged and complicated evolutionary process as yet not fully explained, despite many recent scientific advances. Although the relatively hospitable savannas of sub-Saharan Africa invariably provided the setting for the emergence of our species, we cannot readily designate a precise period in world history when our behavior became truly human, unless it would be the tremendous evolutionary leap that occurred during the Upper Paleolithic.

Human Rights

After World War II, those building a new international legal structure understood that protecting the human rights of all people was necessary to avoid future global conflagrations. The spread of democracy further boosted human rights issues. Although nations continue to disagree about the universality of certain human rights, a clear global consensus has emerged about the need to recognize the fundamental rights of every individual.

Human rights have emerged as a major subject of international law since 1945. Before World War II, the international community gave little attention to how a country treated its own citizens within its own borders. This reluctance ended after the world witnessed the horrors committed by Germany against its own citizens during World War II, as well as by Germany and Japan against the citizens of the countries they occupied.

Historical Background

The focus on individual rights in Europe evolved over centuries as monarchs began to recognize the political and economic rights of at least some individuals. In England, the Magna Carta in 1215 and events in subsequent centuries gradually gave wealthy male property-owners some rights that they could assert against the crown. The American Declaration of Independence in 1776 declared that “all men are created equal,” but all of the original thirteen states in fact granted rights only to white males, and many only to male property-holders; African slaves, Native Americans, and women were granted no rights

to participate in political decision-making. Slavery was not eliminated until almost nine decades after the United States declared its independence; women were not given the vote until 1920; and Native Americans were not finally accepted as U.S. citizens until 1924.

Like the American Revolution, the French Revolution in 1789 was based on concepts of individual liberty, and some European writers of the time articulated the watershed idea of a government, based on the consent of the governed, that would protect the worth of each individual. France and the other European nations moved slowly, however, in the direction of any real recognition of individual equality.

Laws of War

Western nations also made efforts in the nineteenth century to reduce the destructive effects of warfare by distinguishing between combatants and noncombatants and by protecting those captured in battle. In the United States, President Abraham Lincoln asked the political philosopher Francis Lieber to draft a code to govern military conduct during the U.S. Civil War (1860–1865). The laws of armed conflict were further developed by international treaties such as those promulgated at the 1899 and 1907 Hague Conferences, which attempted to protect civilians in time of war and focused on prohibiting the use of weapons that caused unnecessary suffering without providing a significant military advantage.

The Geneva Conventions of 1929 provided a comprehensive and widely ratified set of treaties designed to protect captives and civilians in warfare. These treaties were revised in the four Geneva Conventions

My humanity is bound up in yours, for we can only be human together. • **Desmond Tutu (b. 1931)**

of 1949 and were further updated through two protocols adopted in 1977.

These early efforts were important in providing some recognition of individual rights, but the real impetus to protect human rights at the international level did not begin until after World War II. The post-war trials of German and Japanese war criminals held in Nuremberg and Tokyo were defining moments in reinforcing the culpability of human rights abuses. Although criticized at the time as “victors’ justice,” that is to say, punishment of the losers of the war by the winners, the careful and dramatic evidentiary documentation of government planning and implementation of systematic wartime atrocities made clear the need to work toward a world where such depravities would “never again” occur.

International Human Rights Law in the Postwar Era

The most important event in the development of contemporary international human rights standards was the establishment of the United Nations in 1945. The United Nations Charter contains two key articles recognizing the importance of protecting the human rights of all individuals: Articles 55 and 56 state that the United Nations and its members shall promote “universal respect for, and observance of, human rights and fundamental freedoms for all without distinction as to race, sex, language, or religion.”

Pursuant to this mandate, delegates representing the founding members of the United Nations, led by the former U.S. first lady Eleanor Roosevelt, drafted the Universal Declaration of Human Rights, which listed the fundamental rights of individuals. This text was promulgated by the U.N. General Assembly in 1948, the same year the Genocide Convention was offered for ratification (the latter came into force in 1951). The Universal Declaration has come to be respected as an authoritative listing of rights, and its provisions are now widely regarded as customary international law.

Many U.N. delegates wanted a formal treaty to give the rights listed in the Universal Declaration

even more force. The ensuing process of treaty drafting took eighteen more years. The United States and others viewed human rights as primarily civil and political rights, designed to allow individuals to participate in political decision-making and to protect them against government abuses. But other countries stressed the additional importance of economic, social, and cultural rights, arguing that food and shelter, for instance, were more basic and more important for those in the developing world than the more abstract civil and political rights. These different categories of rights require different mechanisms of enforcement, because economic rights can be protected only through the expenditure of money; thus, the enforcement of economic rights is commonly regarded as best undertaken by legislative bodies balancing competing priorities, rather than by courts with no budgetary responsibility.

Because of differences such as these, it was decided to prepare two separate treaties, and in 1966 the U.N. General Assembly promulgated both the International Covenant on Civil and Political Rights and the International Covenant on Economic, Social, and Cultural Rights.

In the first treaty, the fundamental civil and political rights include the right to life; the right to freedom from torture and cruel, inhuman, and degrading treatment; the right to freedom from slavery; the right to freedom from arbitrary arrest and detention; the right to equal treatment without regard to race or sex; the right to participate in political decision-making, directly or through chosen representatives; the rights to freedom of thought, conscience, and religion; the rights to freedom of opinion, expression, association, and assembly; the right to privacy; the right to freedom of movement; and the right to fair procedures in criminal, civil, and administrative matters.

The International Covenant on Civil and Political Rights is overseen by the Human Rights Committee, an eighteen-member body based in Geneva, Switzerland, with members elected by the countries that have ratified the treaty. Ratifying nations provide regular reports regarding their human rights record to the committee, and individuals can bring complaints

against their own government, if the government has also ratified the Optional Protocol to the Covenant. The opinions issued by the committee are influential in clarifying the rights in the treaty and can be used by the complaining parties in their national courts. Complaints can also be filed by one country against another under Article 41 of the covenant.

The fundamental economic, social, and cultural rights in the second treaty include rights to free choice of employment and to form and join trade unions; rights to education, food, housing, and health care; the right to rest and leisure; and the right to participate in the cultural life of the community. Again, ratifying countries are expected to prepare reports regarding their protection of these rights, and the committee established to review these reports issues opinions to provide guidance to the ratifying countries.

Groups of people also have human rights recognized under international law: Article 27 of the International Covenant on Civil and Political Rights recognizes the right of members of ethnic, religious, and linguistic minorities to enjoy their own culture, practice their religion, and use their own language. Indigenous people who are not self-governing also have the right to self-determination. Other rights generally recognized as important, but whose specific content and means of enforcement continue to evolve, include the right to a clean and healthful environment, the right to economic development, and the right to peace.

In addition to these global covenants, many specialized treaties addressing specific human rights areas have been promulgated by the international community including the 1951 Convention Relating to the Status of Refugees (and its 1967 Protocol), the 1966 International Convention on the Elimination of Racial Discrimination, the 1979 Convention on the Elimination of All Forms of Discrimination Against Women, the 1984 Convention Against Torture and Other Cruel, Inhuman, or Degrading Treatment or Punishment, the 1989 Convention on the Rights of the Child, and the 1989 International Labor Organization Convention Concerning Indigenous and Tribal Peoples in Independent Countries. Also of substantial

importance are the three regional human rights treaties: the European Convention for the Protection of Human Rights and Fundamental Freedoms, the American Convention on Human Rights, and the African Charter on Human and Peoples' Rights.

The European Court of Human Rights issues opinions binding on the European nations, and it has evolved into a court of last resort on a wide range of important and controversial issues. In the 2003 case of *Lawrence v. Texas*, the U.S. Supreme Court cited some of these European cases to provide support for a ruling that declared a Georgia law banning sodomy unconstitutional. The American Convention on Human Rights is overseen by a seven-member commission and a seven-member court, both based in San Jose, Costa Rica. Although this convention has not yet attained the near-universal ratification of the European Convention, the Inter-American Human Rights Commission and Court have issued numerous important opinions bringing clarity to human rights principles applicable in the Western Hemisphere.

Also helping to identify and protect human rights is the United Nations Commission on Human Rights, a body that reports to the U.N. Economic and Social Council (ECOSOC). The Human Rights Commission consists of fifty-three government representatives elected by ECOSOC for three-year terms. It meets in Geneva for six weeks each spring to discuss specific human rights violations, initiate studies and fact-finding missions, and draft conventions and declarations.

Universal Jurisdiction

Because international and regional enforcement mechanisms (with the exception of the European Court of Human Rights) remain somewhat primitive and inadequate, some human rights victims have attempted to utilize national courts to bring claims against human rights abusers. These cases have been brought under the theory of "universal jurisdiction," which allows those who violate the most fundamental human rights to be sued and prosecuted in any jurisdiction where they are found.

In London, in 1998, masked protestors demand that General Augusto Pinochet be returned to Chile to answer war crimes' charges.

U.S. federal courts have adjudicated a number of universal jurisdiction claims, utilizing jurisdiction provided by the Alien Tort Claims Act, which was enacted by the First Federal Congress in 1789, and the Torture Victim Protection Act, enacted in 1992. A claim was brought in 1986 in the federal court in Hawaii, for example, by a class of 9,500 victims of torture, murder, and disappearance in the Philippines during the dictatorial regime of Ferdinand Marcos, which lasted from 1972 to 1986. A U.S. federal jury determined that Marcos was personally liable for these atrocities, and awarded the class members \$775 million in compensatory damages and \$1.2 billion in exemplary or punitive damages. Efforts to collect this judgment have been frustrated, but are continuing.

Other countries, including Spain and Belgium in particular, have also utilized universal jurisdiction to bring human rights abusers to justice. In late 1998, after former Chilean dictator general Augusto Pinochet arrived in London for a herniated disc operation, a Spanish judge asked the United Kingdom to extradite him to Spain for prosecution for torture and murder during his seventeen-year rule from 1973 to 1990. The British House of Lords ruled that Pinochet did not have any immunity from such prosecution and that he should be extradited, but the transfer never took place because of Pinochet's declining health.

In the 1990s, the U.N. Security Council established criminal tribunals to prosecute those who had

committed war crimes, crimes against humanity, or genocide during the civil war in the former Yugoslavia and the ethnic slaughter in Rwanda. More recently, tribunals utilizing both local and international judges have been established to prosecute those who engaged in criminal behavior in Sierra Leone and East Timor, and efforts are continuing to establish a similar tribunal in Cambodia.

To establish a permanent court to deal with future systematic abuses, the countries of the world met in Rome in the summer of 1998 to draft a treaty creating an International Criminal Court. The treaty needed sixty ratifications, which were obtained relatively rapidly, and the court came into existence in March 2003, when its eighteen judges from all over the world were sworn in. The International Criminal Court has jurisdiction over war crimes, crimes against humanity, and genocide, and it will gain jurisdiction over the crime of aggression, after that term is defined in further detail. Although some important nations, including the China, India, Russia, and United States, remain reluctant to ratify the court's statute as of 2010, its establishment stands as a landmark achievement in the quest to protect human rights globally.

Human Rights in the Twenty-First Century

Although nations continue to disagree about the universality of certain human rights, a clear global

consensus has emerged about the necessity of protecting the fundamental rights of every individual. The nations of the world have made enormous strides in defining these rights during the past sixty years. Although the mechanisms for protecting human rights are still evolving, the mix of national, regional, and international tribunals currently being employed to prosecute wrongdoers and provide compensation for victims is beginning to show promise. The dream of having a world where every individual's rights are protected has not yet been attained, but progress toward that goal is continuing.

Hygiene

Hygiene, in its modern sense the act of personal and domestic cleansing, is an adaptive behavior practiced by insects, birds, fish, and animals (including humans); organisms that can best reduce the costs of disease through the avoidance of parasites become more evolutionarily “fit.” Hygienic behavior in humans has been culturally elaborated to serve symbolic, ritual, and moral functions.

Hygiene is the set of behaviors that keeps individuals and their environments clean, especially to prevent infection. The word hygiene has narrowed its meaning through history. Its roots are Indo-European; *hy* is thought to have meant “well” and *gies* to have meant “live.” The Greek word *hygies* means “in good health” or a force “good for health, promoting health.” Hygieia, daughter of Asclepius, was the Greek goddess of health (Parker 1983). Hygiene still had this broader connotation as the science of public health in the Anglophone world of the nineteenth and twentieth centuries, but in recent decades it has taken on a narrower sense as personal and domestic cleaning, and some now use it even more narrowly to denote behavior or rituals involved in avoiding germs.

All animals, including humans, exhibit hygienic behavior because it is adaptive. Animals are under constant pressure from microparasites such as viruses, fungi and bacteria, and macroparasites such as nematodes (roundworms), helminths (intestinal worms), and insects that are seeking nutrition, shelter, and reproductive opportunities within, or on, their bodies. Those animals that can best reduce the costs of disease through the avoidance of parasites do best in the evolutionary fitness stakes, all else being equal.

Hence, animals invest energy in carrying out the hygienic behaviors that serve to detect, deter, avoid, and remove damaging parasites from their bodies and environments. In humans hygienic behavior has been culturally elaborated beyond these basic functions to serve symbolic, ritual, and moral functions.

Animal Hygiene

To judge from its ubiquity today, hygienic behavior is probably almost as old as animal life itself. So, for example, the simple nematode worm *Caenorhabditis elegans*, which has only 302 neurons, can detect the presence of a parasitic species of bacterium in its petri dish and flee from it. Insects display many hygiene behaviors. Social insects such as ants and termites groom each other, and they build nests using materials that incorporate antifungals and antibacterials. Many social species employ separate castes to carry wastes, as well as the sick and the dead, to dung-hills; if an ant relegated to the status of a “cleaner” tries to contact other ants it is repulsed with aggression (Holldobler and Wilson 1990). Insects avoid fouling their ranges with their own feces (frass) by shooting it out, flicking or pushing it away, walling it up in their webs, or disposing of it in disused tunnels (Weiss 2006). Lobsters make sure their dens are clean and ventilated; the gregarious Caribbean spiny lobster demonstrates social hygiene by refusing to share a den with others infected with the lethal PaV1 virus. Similarly, killifish avoid shoaling with other fish that appear to have parasites. In the Red Sea, the surgeonfish stops feeding on the reef every five to ten minutes and swims to a spot beyond the reef edge to defecate. Reptiles demonstrate similar

The chickadee's nest. Parent birds remove excrement, eggshells, foreign debris, and ectoparasites from nests to preserve the health of their offspring. From *In the Morning Glow* by Roy Rolfe Gilson, illustrated by Alice Barber. New York: Harper, 1903. New York Public Library.

behaviors. Geckos, for example, defecate around the edges of their territories. Bullfrog tadpoles avoid other tadpoles that have a dangerous yeast infection. Salamanders that observe the food hygiene practice of not cannibalizing others reduce the risk of acquiring parasites.

Birds, such as the oystercatcher, are careful to avoid eating food that may contain parasites. Nestlings are particularly vulnerable. Parent birds therefore remove nestling excrement, eggshells, foreign debris, ectoparasites, and dead nestlings from their nests. Parent birds defecate away from nests; penguins, for example, can shoot out a projectile excrement that hits the ground about half a meter away from the nest, making stains that are used in biodiversity monitoring by satellite. The Great Tit, a common woodland species in Europe, cuts down on sleep to clean its nest if nestlings have a heavy infestation of fleas. Blue tits, falcons and starlings bring fragments of aromatic plants, which contain the same active compounds used by humans to make house cleaners and herbal medicines, to their nests. More than 250 bird species

are known to “ant,” that is, to rub crushed insects over their plumage. This behavior distributes compounds such as formic acid that protect from parasitic bacteria, fungi, and arthropods.

Mammals demonstrate myriad hygienic behaviors including: nest cleaning (badgers change nest material regularly); selective feeding (sheep avoid eating from patches of grass that are heavily dosed with dung); avoiding the sick of their species (female house mice distinguish the smell of sick males and refuse to mate with them); feces disposal (blind mole rats have latrine chambers; tapirs, badgers, raccoons, and lemurs use latrine sites); and grooming behavior (impala use their teeth to comb off lice). It seems that the reindeer’s annual migration may even be for hygienic purposes—moving in response to the build up of dung in calving grounds.

Primates are well known for grooming each other. Chimpanzees keep themselves clean too, for example, by engaging in penile hygiene—wiping themselves off with leaves after mating—while mother chimps sometimes wipe the behinds of their infants who have just defecated. Colobus monkeys rub their fur with the juices of leaves and fruit, probably to deter parasites, and many primate species avoid defecating on, or near, food plants. Primate troops limit their size, especially in parasite-dense ecozones, and quarantine new members until it is clear that they are healthy.

Extant animals across taxonomic groups thus demonstrate food hygiene (avoiding the consumption of parasites), personal hygiene (removing and discouraging ectoparasites), social hygiene, (avoiding contact or sex with sick others or outsiders who may be harboring parasites), and domestic hygiene (removing parasites, vectors [hosts], and parasite-containing wastes from the living environment). Some sedentary and social animals also display sanitary behavior (constructing a niche that is not conducive to parasites).

Human Hygiene

As recently evolved primates, *Homo sapiens* have inherited the gamut of food, social, personal, domestic, and sanitary hygiene behaviors from their ancestors.

Ancient Roman baths and bathing implements. Bathing in Rome was a communal activity, and public baths often included libraries or lecture halls.

This behavior is proximally motivated by disgust, an emotional reaction triggered in the brain which causes the avoidance of micro- and macroparasites (Curtis 2004). (The psychological systems that motivate animal hygiene behavior have been little studied, but presumably involve some form of proto-disgust.)

Disgust is universal in humans, as is hygienic behavior. It is thus likely that ancient humans, unlike their caricature, would have been hygienic. But evidence of early hygienic behavior among humans is hard to come by. The earliest signs of the interment of the dead date from the Middle Palaeolithic era. Neanderthals used seashell tweezers, possibly to pluck hair, and early cave paintings show beardless men, suggesting that grooming was common, perhaps to remove facial parasites. Hygiene artifacts are amongst the earliest material goods recovered; for example, an ivory comb in the collection of the Metropolitan Museum of New York dates from predynastic Badarian Egypt (3200 BCE). A Babylonian letter of the seventeenth century BCE counsels not sharing a chair, a bed, or a cup with a lady suffering from a disease. Excavations of the earliest city states of the

Indus basin dating from 3000 BCE found drainage structures, and early Minoan and Roman plumbing and toilet facilities are well documented.

Cleansing aids have a long history. Early cave dwellers may have discovered they could remove stubborn stains with the residue of fat and ash left over from roasting meat. The first recorded use of soap, however, is from Babylonian times, although the use of oil and a scraper was a more common way of cleaning the skin in the Greek and Roman eras.

Ritual and Religious Purification

While the above examples show an early concern for material hygiene, with the dawn of written records comes evidence of a further aspect of hygiene. Imaginative humans began to find the *idea* of hygiene useful in symbol and ritual. Disgust is a powerful emotion with seemingly magical properties. It is not just elicited by dead bodies, unfit food, bodily wastes and fluids, certain animals, and signs of sickness, but also by everything that has come into contact with such things—that is, anything that is contaminated (Rozin 2008). It is also elicited by moral violations (perhaps because disgust helps condemn immoral acts that are akin to social parasitism).

Early religions wove hygiene rules into their prescriptions for correct behavior. In ancient Egypt priests had to maintain immaculate purity by washing from head to foot twice every day and twice every night. The Semitic religions employ purificatory rituals such as “Kippuru,” the washing off of a specially applied paste, to remove material and moral pollution. Greek texts prescribed purificatory rituals to cleanse the pollutions of childbirth, death, sex, and murder (Parker 1983). Failure to cleanse a moral pollution could bring down the wrath of the gods. For example, in Sophocles’s ancient Greek drama *Oedipus the King*, a plague is visited on Thebes because of Oedipus’s sin in killing his father and marrying his mother. Oedipus’s stain (miasma) is purged by his self-blinding and exile.

The Laws of Manu, part of the four sacred Vedas of Hindu scripture (c. 200 BCE), prescribed the

Oil on oak.

avoidance of the twelve impurities of the body: oily exudations, semen, blood, urine, feces, the mucous of the nose, ear wax, phlegm, tears, the rheum of the eyes and sweat. Similarly, Leviticus 11–16 provides detailed rules about purity and impurity, listing, for example, animals that are clean and unclean, unclean bodily fluids, and unclean acts requiring ritual purification.

Mary Douglas's influential work on purity and pollution argues that such rules about impurity are byproducts of the ways in which societies organize themselves. She writes: "Dirt then, is never a unique, isolated event. Where there is dirt there is a system. Dirt is the by-product of a systematic ordering and classification of matter, in so far as ordering involves rejecting inappropriate elements" (Douglas 1966, 35).

But as we have seen, rules about pollution and contamination arise out of ancient hygiene instincts, driven by the evolved emotion of disgust, and so they cannot be explained purely as a product of culture. Although there is some limited variation between cultures in the substances and events labeled as "polluting," overall the historical and ethnographic record shows patterns that are consistent, with the

instinctual avoidance of those objects and situations where the risk of parasitic infection is highest.

Hygiene in Recent History

Prescientific thinking about hygiene had the gods intervene to punish pollutions. Secular beliefs—about contaminating bad airs or miasma as a cause of disease—replaced this thinking and continued to hold sway in western Europe for over 2000 years. Eventually those ideas too gave way to germ theory. There is much debate over the details of how and when the germ theory of disease took hold. A key development was, of course, the microscope. Yet it was more than three hundred years after Anton van Leewenhoek (1632–1723) demonstrated the teeming animalcules in the white matter between his "usually very clean" teeth that belief in germs became an established norm in Western medical discourse. The idea that invisible living organisms were responsible for disease spread in fits and starts through Europe and America over the second half of the nineteenth century.

This epidemiologic spread of Western ideas into other cultures was underpinned by the same intuitive concern for hygiene—that it could not be good for one to be invaded by disgusting tiny insects, fungus, or seeds (germs). It gained ground because it was taught by respected others who were known to have real cures for disease—in this case, the powerful colonizers, with their science and their microscopes. Nevertheless, germ theory spread unevenly across much of the world, sometimes to replace, and sometimes to live side-by-side, or hybridize with, local beliefs about the origins of disease. For example, in Burkina Faso, the intuition that dirt causes disease is well established. Diarrhea in children is thought to be caused by contamination of the mothers' milk by sperm if sexual relations have been resumed postpartum and by worms. But only *toubaboukonoboli*, translated as "white's diarrhea," is attributed to germs.

Hygienic behavior is universal in modern humans (Brown 1991). Irrespective of their knowledge of, or belief in, germs, every cultural group that has been

studied demonstrates and values food, personal, social, and domestic hygiene. While economic and scientific development has led to major improvements in environmental health and hygiene in the

West, epidemiological studies show that greater investment is needed in public health and hygiene in less developed countries. The widespread adoption of hand washing with soap, the removal of fecal contamination from water, better food hygiene, and the provision of modern sanitation systems could still save many millions of lives from infectious diseases in developing countries (Curtis and Cairncross, 2003).

I Ching (*Classic of Changes*)

The text known as the *I Ching* (*Classic of Change*; or *Yijing*) originated in China about three thousand years ago. It profoundly shaped East Asian thought, was adapted as one of the five Confucian classics, and eventually came to influence writers and thinkers worldwide. As a book about divination and the source of wisdom, it is both a repository of moral and political insight and a guide for individual self-fulfillment.

The Chinese text *I Ching* (*Classic of Changes*), exemplifies the process by which great and enduring philosophical and religious texts (classics) evolve in one cultural environment and are then transmitted to, and often transformed by, other environments. (*I Ching* is the Wades-Giles transliteration that became, and still is, widely used; *Yijing* is the more recent pinyin transliteration. The *I Ching* is also commonly translated in English as the *Book of Changes*.) Originating in China as a primitive divination text three thousand years ago, the *I Ching* found its way to many parts of eastern Asia from about the sixth century CE onward. Beginning in the seventeenth century, it traveled to Europe and eventually the Americas. Today, translated into several dozen languages, the *I Ching* continues to be consulted by millions of people throughout the world.

What sort of a text is the *I Ching*, and how did it come to exert such a pervasive global influence? The ancient “basic text” consists of sixty-four six-line symbols known as “hexagrams” (*gua*). The theory of the *I Ching* is that these hexagrams represent the basic circumstances of change in the universe and that by consulting the text with a reverent spirit, one can select a hexagram that will provide guidance for the present and the future.

Each hexagram has a name (*guaming*) that refers to a physical object, an activity, a state, a situation, a quality, an emotion, or a relationship; thus Ding (Cauldron), Dun (Retreat), Meng (Youthful Ignorance), Yu (Enthusiasm), Song (Conflict), Tongren (Human Fellowship), and so forth. In addition, each hexagram possesses a short, cryptic description of several words, called a “judgment” (*tuan* or *guaci*). Finally, each line of every hexagram has a brief written explanation (*yaoci*) of that line’s developmental position and symbolism. Through a sophisticated analysis of line relationships and other variables, a person could not only “know fate” (*zhiming*) but also “establish fate” (*liming*)—that is, devise a successful strategy for dealing with any cosmically mandated situation.

The “Ten Wings”

During the early Han dynasty (206 BCE–220 CE) a set of poetic commentaries known as the “Ten Wings” became permanently attached to the *I Ching*, and the text received imperial sanction as one of the five major Confucian classics. These Ten Wings—particularly the so-called Great Commentary (*Dazhuan* or *Xici zhuan*)—articulated the *I Ching*’s implicit cosmology (a branch of metaphysics that deals with the nature of the universe) and invested the classic with a new philosophical flavor and an attractive literary style. The worldview of this amplified version of the *I Ching* emphasized correlative thinking, a humane cosmological outlook, and a fundamental unity between heaven, Earth, and people. For the next two thousand years or so the *I Ching* held pride of place in China as the “first of the [Confucian] classics.”

Diagrams from the *I Ching*. The Luo Shu diagram (top left) and He Thu diagram (top right) represent a simple magic square and a cruciform array of the numbers from 1 to 9. Even (yin) numbers are represented in black and odd (yang) numbers in white. In the Luo Shu magic square (bottom left) the numerals add up along any diagonal, horizontal line, or column to 15. The He Thu squares (bottom right) are rotated so both odd and even number sets (excluding the central 5) add up to 20.

In the fashion of classic texts in other major civilizations, the *I Ching* had a profound effect on Chinese culture from the Han dynasty to the end of the imperial era (1912 CE) in areas such as philosophy, religion, art, literature, political life, social customs, and even science. Thinkers of every philosophical persuasion—Confucians, Daoists, and Buddhists alike—found inspiration in the language, symbolism, imagery, cosmology, epistemology (the study or a theory of the nature and grounds of knowledge), ontology (a branch of metaphysics concerned with the nature and relations of being), and ethics of the *I Ching*. The *I Ching* also inspired a landslide of artistic and literary productions and provided an analytical vocabulary that proved extraordinarily serviceable in a wide variety of realms. During pre-modern times Chinese “scientists” used hexagram symbolism and *I Ching*-derived numerology (the study of the occult significance of numbers) and mathematics to explain a wide range of natural processes and phenomena in fields of knowledge that are today’s physics, astronomy, chemistry, biology, meteorology, and geology.

The *I Ching*’s great prestige and multifaceted cultural role in China commended it to a number of civilizations on the Chinese periphery—notably, Korea, Japan, Vietnam, and Tibet. In all of these

environments the *I Ching* enjoyed an exalted reputation and was employed in a variety of cultural realms. Not surprisingly, through time the *I Ching* came to be used and understood in ways that reflected the particular needs and interests of the “host” environment, and in the process the *I Ching* became less of an alien “Chinese” document and more of a “domestic” one. Thus, for example, its symbolism came to be used in Japan to express distinctively Japanese sensibilities, such as those connected with the tea ceremony and flower arranging. This process of domestication also allowed a scholar such as Jiun Sonja (1718–1804), who claimed that “every word of the *Ekikyo* [*I Ching*] is interesting and significant,” to argue that “the whole book has been completely borrowed [by the Chinese] from us [the Japanese]” (Ng 2000, 107).

Similar processes of appropriation and adaptation took place in the West. A group of seventeenth-century Jesuit priests known as “Figurists” made the earliest effort to bring the *I Ching* to the attention of Europeans (and at the same time to bring the Bible to the attention of the Chinese). The most prominent among these priests was Father Joachim Bouvet (c. 1660–1732). A significant part of the Figurist mission was to show, by fancy philological footwork, that the Bible and the *I Ching* were umbilically related. Thus, for instance, the three unbroken lines

This bronze mirror of the Tang dynasty, inspired by the *I Ching*, depicts constellation diagrams, the twelve animals of the zodiac, and the four symbolic animals of the Celestial Palaces.

Collection of American Museum of Natural History.

of the Qian (Heaven) trigram indicated an early Chinese awareness of the Trinity, and the hexagram Xu (Waiting), with its stark reference to “clouds rising up to Heaven,” symbolized the “glorious ascent of the Saviour.” Bouvet’s correspondence with the German mathematician Wilhelm Gottfried von Leibniz (1646–1716) led Leibniz to see striking similarities in the configuration of the “broken” and “unbroken” lines of the hexagrams in the *I Ching* and his own binary mathematical system.

In more recent times efforts to find a place for the *I Ching* in Western culture have continued unabated. During the 1960s in particular, translations of the book appeared in many parts of the Western world (and elsewhere), embraced by countercultural enthusiasts alienated from their own political, social, and philosophical traditions and searching for fresh answers to timeless or pressing questions. Meanwhile, creative thinkers in the arts and the sciences have used the *I Ching* either as inspiration or as a transcultural validation of their own original ideas.

Influence on the West

The *I Ching* thus influenced many realms of modern Western life, from the psychology of Carl Jung to the architecture of I. M. Pei. The choreographers Merce Cunningham and Carolyn Carlson have found inspiration in the *I Ching*, as have such noted composers as John Cage and Udo Kasemets. It has been a significant element in the art of people such as Eric Morris and the writings of a wide range of Western authors, including Philip K. Dick, Allen Ginsberg, Octavio Paz, Raymond Queneau, and Fritjof Capra. In the realm of

“pop” culture the *I Ching* has served as a vehicle for the expression of an array of ideologies, outlooks, and orientations, from feminism (*A Woman’s I Ching*) to sports (*Golf Ching*).

We may assume that the *I Ching* will continue to inspire creativity, in both East and West, for the same reasons it has inspired creativity in the past: its challenging and ambiguous basic text, which encourages interpretive ingenuity; its elaborate numerology and other forms of symbolic representation; its utility as a tool of divination; its philosophically sophisticated commentaries; its psychological potential (as a means of attaining self-knowledge); and its reputation for a kind of encyclopedic comprehensiveness. For those people who take the text seriously and approach it with intellectual depth and psychological insight, it will no doubt remain a stimulating document; then again, those people of a shallower intellectual or psychological disposition may put the *I Ching* to more superficial uses. In the words of a Chinese proverb, “The shallow man sees [the *I Ching*’s] shallowness, while the deep man sees [its] depth.”

Ibn Battuta

(1304–1368/1369)

ARAB SCHOLAR AND TRAVELER

Ibn Battuta, an Arab scholar and traveler, has garnered more recognition for his travel journals than Marco Polo. The accounts of his journeys in Eurasia and Africa, which record observations of nearly every conceivable facet of life in the fourteenth century, illuminate the values, customs, and cosmopolitanism of educated Muslims in the late Mongol era.

Among travelers of premodern times who have left any record of their adventures, Abu ‘Abd Allah Muhammad ibn ‘Abd Allah al-Lawati at-Tanji ibn Battuta is unrivaled for distance covered and sights seen. The account of his journeys in Eurasia and Africa between 1325 and 1354 is one of the most absorbing and historically valuable documents to come down to us from the medieval era. His *Rihla* strikingly reveals both the far-flung cosmopolitanism of Muslim civilization in the fourteenth century and the dense networks of communication and exchange that linked together nearly all parts of the Eastern Hemisphere at that time.

Born in Tangier, Morocco, in the time of the Marinid dynasty, Ibn Battuta grew up in a family known for careers in legal scholarship. He received an education in the religious sciences, literature, and law befitting a young Arab gentleman. In 1324, he left Morocco to perform the holy pilgrimage (hajj) to Mecca in western Arabia. Initially, he may have intended to study Islamic law in Cairo or one of the other Muslim university centers, and then return home to a respectable career in jurisprudence. Instead, he set forth on a remarkable twenty-nine year odyssey that took him from what is now Tanzania to Kazakhstan and from the South China

Sea to tropical West Africa. He traveled by donkey, horse, camel, wagon, and ship, covering in all 116,000–120,000 kilometers. His account of his adventures includes numerous delights, tribulations, and brushes with death. He was shipwrecked off the coast of Sri Lanka, lost in a mountain blizzard in Anatolia, captured by Indian bandits, attacked by pirates off the Malabar Coast, nearly executed by the Sultan of Delhi, infected with disease, and drawn into a plot to overthrow the government of the Maldive Islands. He also married and divorced several times, bought and sold slaves, fathered children, and sat in audience with Mongol monarchs.

Everything we know about Ibn Battuta’s routes and destinations is to be found in the narrative he produced at the end of his traveling career. The itinerary and chronology as he reports them are complex and often puzzling, but despite numerous uncertainties, we may with some confidence group the travels into ten major periods:

1. 1325–1326. Tangier to Mecca by way of Cairo and Damascus.
2. 1326–1327. Mecca to Iraq, western Iran, and back to Mecca.
3. 1328–1330. Mecca to Yemen, East Africa, South Arabia, the Persian Gulf, and back to Mecca.
4. 1330–1333. Mecca to Syria, Anatolia, the Pontic-Caspian steppes, Byzantium, the Volga River valley, Transoxiana (in present-day Uzbekistan), Afghanistan, and North India.
5. 1333–1341. Residence in the Sultanate of Delhi and travels in North India.

6. 1341–1345. Delhi to Gujarat, Malabar, the Maldiv Islands, Ceylon (present-day Sri Lanka), and Bengal.
7. 1345–1347. Bengal to Indochina, Sumatra, and southern China.
8. 1347–1349. Southern China to Sumatra, Malabar, the Persian Gulf, western Iran, Syria, Egypt, Mecca, Tunis, and Morocco.
9. 1349–1351. Travels in Morocco and southern Spain, including visits to Fez, Tangier, Gibraltar, Granada, Salé, and Marrakech.
10. 1351–1354. Sijilmasa on the northern fringe of the Moroccan Sahara to the West African Sudan, and back to Fez.

The relatively stable political conditions that prevailed in many parts of Afro-Eurasia in the second quarter of the fourteenth century no doubt facilitated Ibn Battuta's prodigious journeys. This was the twilight of the age of Mongol dominance. When he began his traveling career, four great Mongol states, three of them Muslim, ruled the greater part of Eurasia. Among other large and flourishing states were the Mamluk Empire in Egypt and Syria, the Sultanate of Delhi in North India, and the Mali Empire in West Africa—all Muslim. Typically, the rulers of these states encouraged long-distance trade and provided security for the interurban journeys of Muslim diplomats, preachers, and scholars, including Ibn Battuta.

Ibn Battuta's motives for travel were many. First, he journeyed as a religious pilgrim. He took part in the rituals of the hajj in Mecca six or seven times during his career, and indeed the Holy City became the central hub of his peregrinations. Second, he traveled to pursue advanced studies in Islamic law, though he attended lectures, as far as we know, only in Damascus and Mecca. Third, he traveled as a devotee of Sufism, the mystical dimension of Islam. He visited a number of cities and Sufi lodges specifically to pay his respects to living scholar-saints or to the tombs of deceased ones, thus sharing in the aura of divine grace associated with them. Fourth, he journeyed to seek employment. In Delhi, he received

generous salaries and honors for serving the Muslim Turkic government as both a judge and a royal mausoleum administrator. For several months he held a judgeship in the Maldiv Islands. We must also accept that his motive for visiting some places, tropical East Africa, for example, was simply that these were parts of the Muslim world he had not yet seen.

According to the scant references to him that appear in other Arabic texts of the fourteenth and fifteenth centuries, he died in 1368 or 1369, after serving in his later years as a judge in an unidentified Moroccan town. A tomb where tradition says he is buried still stands in the heart of Tangier. The Moroccan scholar Abelhadi al-Tazi has recently reported documentary evidence suggesting that the traveler's bones may rest in Anfa, a port town that today lies beneath modern Casablanca.

Ibn Battuta identified himself with the Muslim learned class (*ulama*), and that status, which he displayed in piety, dress, social manners, and religious knowledge, gained him entry to the homes and princely courts of the powerful and rich. We have no evidence, however, that he was an especially accomplished intellectual. When he ended his traveling career in Fez, he wrote the account of his adventures in collaboration with Muhammad Ibn Juzayy (1321–1356 or 1358), a young Moroccan scholar, who had skills Ibn Battuta did not possess to compose the travels in proper literary form.

Formally titled "A Gift to the Observers Concerning the Curiosities of the Cities and the Marvels Encountered in Travels," the *Rihla* circulated in manuscript form among educated North Africans in the fourteenth century and in West Africa, Egypt, and possibly Syria in subsequent centuries. In the mid-nineteenth century, French scholars discovered manuscript copies of the *Rihla* in Algeria and prepared both a printed Arabic text and a French translation. Since then, the account has been translated into English, Spanish, German, Persian, and several other languages. In recent years, Ibn Battuta has become more widely known in Western countries owing to publication of popular articles about him and to his inclusion in most encyclopedias and world history textbooks.

This section of the famous Catalan Atlas, the most important map of the medieval period, shows the Middle East in 1375, a territory Ibn Battuta explored (beginning fifty years earlier) during his long odyssey.

The *Rihla* is of immense documentary value, partly because it illuminates the values, customs, and cosmopolitanism of educated Muslims in the late Mongol era and partly because Ibn Battuta recorded observations of nearly every conceivable facet of life in Muslim and in some measure non-Muslim societies. His subjects of lively and sometimes critical commentary include religion, education, state politics, royal ceremony, law, warfare, gender relations, slavery, trade, agriculture, cuisine, manufacturing, geography, transport, and the achievements and failings of numerous jurists, theologians, monarchs, and governors. The *Rihla* is the only surviving eyewitness account from the fourteenth century of the

Maldivian Islands, Sudanic West Africa, and several other regions.

The book belongs to the genre of literature known as *rihla*, that is, an account of journeys usually centered on a pilgrimage to Mecca. This genre flowered in North Africa and Muslim Spain between the twelfth and fifteenth centuries, and Ibn Battuta's text is the most ambitious representation of it. Scholars agree on the authenticity and reliability of the *Rihla* in general, and independent sources have corroborated many of the traveler's detailed observations. Even so, the itinerary and chronology present numerous inconsistencies and conundrums, and the journeyer's statements are sometimes inaccurate. Parts of the descriptions of

Syria, Iraq, and Arabia are copied, usually without attestation, from at least two other earlier travel accounts, though we cannot be sure how much responsibility for this borrowing might lie with Ibn Juzayy or later copyists. Scholars have also concluded that the accounts of journeys to Bulghar on the upper Volga River, to the city of Sanaa in Yemen, and to northern China are almost certainly fabrications. Moreover, debate continues regarding the trustworthiness of Ibn Battuta's claim to have visited any part of China. Nevertheless, the *Rihla* is a preeminent source for fourteenth-century world history, and because its author reveals so much about his own personality, attitudes, and opinions (far more than does his near contemporary Marco Polo), the narrative continues to captivate modern readers.

Ibn Khaldun

(1332–1406) ARAB HISTORIAN

Ibn Khaldun (1332–1406) is widely regarded as the greatest Arab-Muslim historian and sociological thinker of the premodern period. His writings have been compared to those of intellectual giants such as Aristotle, Thucydides, Ibn Rushd (Averroes), Machiavelli, and Vico, as well as to world historians of the twentieth century.

While the fame of Ibn Khaldun (or Abu Zayd ‘Abd ar-Rahman ibn Khaldun) is largely a result of his historical and sociological thought, he also led a career as a well-traveled statesman, which included the kind of cross-cultural encounters normally associated with the great premodern travelers Marco Polo (1254–1324) and Ibn Battuta (1304–1368/69).

Ibn Khaldun’s family came to Spain during the Arab conquest of the Iberian Peninsula. During their four centuries in Spain, they served under the Umayyad, Almoravid, and Almohad dynasties, holding high positions in administrative and military affairs. His family left Spain in 1248 and settled in North Africa.

Ibn Khaldun was born in Tunis. His father, himself a scholar, ensured that Ibn Khaldun received a thorough education, rooted in the study of the Qur’an, Arabic grammar, and jurisprudence. Ibn Khaldun took particular interest in his teachers, chronicling their lives and the subjects that they taught. But in 1349, the seventeen-year-old Ibn Khaldun lost his great mentors and parents to the Black Death, the great plague that ravaged Afro-Eurasia in the fourteenth century. Ibn Khaldun later came to recognize the Black Death as a contributing factor to the political instability of Muslim regimes in Spain and North Africa during the fourteenth century.

In 1350 Ibn Khaldun began a chaotic odyssey through North Africa and Muslim Spain. From 1350 to 1375, he served numerous masters as secretary, ambassador, and chamberlain, was imprisoned, and even lived among the Bedouin tribes of Algeria. In 1362 he crossed into Granada, entering into the service of the sultan of Granada as an ambassador to the Christian king of Castille, Pedro the Cruel. Ibn Khaldun’s mission went so well that he was offered a position in Pedro’s service. Although he declined to serve in Christian Castille, Ibn Khaldun’s experience in Christian Spain offers historians an illuminating, non-European view of the Christian expansion into Muslim Spain.

After an intense quarter-century of political life, Ibn Khaldun retired to the castle of Qal’at ibn Salama (near present-day Frenda, Algeria) in 1375. He began writing his massive seven-volume historical work, *Kitabal-‘ibar* (Universal History), which includes his masterpiece, the *Muqaddimah* (Prolegomena to History). The *Kitab al-‘ibar* also contains a definitive history of North Africa as well as a candid autobiography, detailing his numerous political and academic appointments. He continued his scholarship until his departure for a pilgrimage to Mecca in 1382, which led him to a new career in Cairo.

In 1382, Ibn Khaldun met the Mamluk sultan of Egypt, Barquq, who appointed him as a lecturer at al-Azhar University as well as the chief *qadi* (judge) of the Maliki school of Sunni Islamic jurisprudence. In 1400, Ibn Khaldun accompanied the sultan as an emissary to the conqueror Timur (Tamerlane, 1336–1405), who was in the process of laying siege to Damascus. Ibn Khaldun’s encounter with Timur illustrates the decline of Arab power in the face of

It should be known that history is a discipline that has a great number of approaches. • **Ibn Khaldun (1332–1406)**

This Tunisian postage stamp commemorates the historian Ibn Khaldun.

Central Asian invaders, yet it also underscores the unity of an Islamic civilization that connected Muslim Spain, Mamluk Egypt, and Turkic-Mongol Central Asia.

In the *Muqaddimah* Ibn Khaldun explored religious, economic, and geographical determinants of social organization. However, the most important element of his science of social organization is *asabiyyah* (social solidarity). He reasoned that small, rural societies have the strongest social cohesion and the potential to become great empires, while large, urbanized states tend to become corrupted by luxury. This weakening of social solidarity led, he theorized, to

economic and social decay, which ultimately caused societies to fall prey to a stronger conqueror. Thus, Ibn Khaldun's astonishingly modern philosophy of history and social organization articulated universal cycles of cultural change and the rise and fall of civilizations.

Although Ibn Khaldun lived and wrote in the fourteenth century, his approach to history foreshadowed that of twentieth-century world historians such as Arnold Toynbee and Oswald Spengler. Like today's world historians, Ibn Khaldun was concerned with cross-cultural interactions, large-scale comparisons between empires, and patterns of history that affect empires and cultures. Therefore, Ibn Khaldun's work is likely to become more widely recognized as the field of world history continues to grow.

Ice Ages

At least five prolonged ice ages—epochs when glaciers cover entire continents—have occurred throughout the Earth’s 4.6 billion-year history. These five ice ages represented unusual, relatively short episodes in the whole of Earth’s climatic record (spanning a total of 50 to 200 million years, only 1 to 4 percent), and yet they destroyed entire ecosystems, leaving behind tremendous piles of glacial debris.

Ice ages are epochs of time when massive ice sheets and smaller ice masses called glaciers cover extensive areas of the Earth’s surface. During an ice age the planet is cold, dry, and inhospitable. Whereas few forests can be supported, ice-covered areas and deserts are plentiful. Winters are longer and more severe, and ice sheets grow to enormous sizes, accumulating to thicknesses that measure thousands of feet in depth. These ice sheets move slowly from higher elevations to lower regions, driven by gravity and their tremendous weight. During that process, they alter river courses, destroy entire regional ecosystems, flatten landscapes, and, along their margins, deposit great piles of glacial debris.

Evidence of Ice Ages

Proof of ice ages—glaciation over continent-sized regions—comes from several sources. There is the widespread deposition of unique sediments of dirt (called “till”) found under melting glaciers. These sediments contain a wide variety of rock forms that have been accumulated from disparate areas. In addition, glaciation leaves telltale marks in the form of grooved, striated, polished bedrock pavements, faceted stones

in the till, and interspersed layers of gravel containing different rock types. Ice ages also are substantiated by erosional forms believed to have been produced by advancing ice sheets, among them sculptured landscapes, such as glacial uplands or U-shaped valleys.

Such evidence suggests at least five prolonged ice ages: (1) during Precambrian era, 1.7–2.3 billion years ago; (2) during the end of the Proterozoic eon, about 670 million years ago; (3) during the middle of the Paleozoic era, about 420 million years ago; (4) during the Carboniferous period, in the late Paleozoic era, beginning 290 million years ago; and (5) during the Pleistocene epoch of the Quaternary period, beginning 1.7 million years ago. In this most recent era, ice sheets developed in the highlands of North America and Europe and dominated the Northern Hemisphere. Massive ice sheets covered all of present Canada, south of the Great Lakes region, as well as Greenland, Scandinavia, and Russia. Each ice age lasted at least a million years, during which great ice sheets migrated back and forth across a huge paleocontinent (ancient or prehistoric continent). The span of these ice ages totaled 50 to 200 million years, which accounts for only 1 to 4 percent of the Earth’s 4.6 billion-year history. Ice ages thus represent unusual, albeit relatively short, episodes in the Earth’s climatic record.

Theories about Causes of Ice Ages

Although scientists have extensively studied glaciation, no single theory is widely accepted as explaining the causes of ice ages. However, several theories converge into two categories. First are terrestrial theories. Among these, in 1941 the Canadian geologist

Illustration of a mammoth from *The Natural History of Man* by A. de Quatrefages, published in 1875. The mammoth's woolly coat allowed it to survive the harsh temperatures of the great ice ages.

and explorer A. P. Coleman suggested that change in the elevations of continents provided a natural explanation for an ice age. That is, the uplifting of continental blocks creates increases in the height of land areas by mountains rising or sea levels falling, which cooled the land and produced glacial conditions. A second theory is linked to the changing continental positions associated with plate tectonics. The notion of continental drift, set out by the German geophysicist Alfred Wegener in 1922, proposes that continents sliding around on the globe's surface could be brought into colder climatic conditions, thereby allowing ice sheets to develop, especially because a continent's climate is mainly determined by its latitude and size. A third theory suggests that extensive volcanic activity, which spews out dust and ash into the atmosphere, reflects radiant solar heat back into space, thereby producing cooler temperatures on the Earth's surface. Closely related is the ocean-atmospheric hypothesis. The assumption here is that the only adequate supply of water for massive ice accumulations is the ocean. Because creation of ice sheets on land depends on wind and weather patterns, logic suggests that profound changes between the ocean and the atmosphere could contribute to the onset of ice ages. Another hypothesis was put

forward in 1998 by the American climatologist, Maureen Raymo. She proposed the idea that Earth's cooling climate over the last 40 million years was caused by a reduction in atmospheric carbon dioxide due to enhanced chemical weathering in the mountainous regions of the world, particularly the Himalayas, and that the growth of the Himalayas may, in fact, have triggered the start of the ice ages.

The second category of theories to explain ice ages is extraterrestrial. As early as 1875 the Scottish scientist James Croll proposed that astronomical variations in the Earth's orbit around the sun produced conditions for the onset of ice ages. He believed that disturbances by the moon and sun cause periodic shifts in the Earth's orbit, thereby affecting the distribution of solar heat received by the Earth and climatic patterns on the surface. Less heat produces colder climates.

Croll's theory was modified in 1938 by a Yugoslav scientist, Milutin Milankovitch, in what is today the most popularly accepted theory for climate changes during the Pleistocene epoch. Milankovitch believed that the amount of solar radiation is the most important factor in controlling the Earth's climate and in producing ice ages. The amount of radiation varies, he argued, according to three key factors. (1) The

Earth doesn't rotate perfectly like a wheel about an axis; it spins like a wobbling top. Every twenty-two thousand years, Milankovitch calculated, there is a slight change in its wobble (called "precession of the equinoxes"). (2) Every 100,000 years there is a change in the Earth's orbit about the sun (which he labeled "eccentricity"). The Earth's almost-circular orbit becomes more elliptical, taking the Earth farther from the sun. (3) Finally, Milankovitch discovered that every forty-one thousand years there is a change in the tilt of the Earth's axis, moving either the Northern or Southern Hemisphere farther from the sun (a process known as "obliquity"). These cycles mean that at certain times less sunshine hits the Earth, so there is less melting of snow and ice. Instead of melting, these cold expanses of frozen water grow. The snow and ice last longer and, over many seasons, begin to accumulate. Snow reflects some sunlight back into space, which also contributes to cooling. Temperatures drop, and glaciers begin to advance. These effects are sufficiently substantial to cause cyclical expansion and contraction of the massive ice sheets. By taking climatic effects and solar insulation of these variations and applying them to computer models of ice sheet behavior, scientists have demonstrated that a correlation exists between these cycles and the cyclic growth and decay of Pleistocene ice sheets over the past 600,000 years. The combination of orbital cycles results in

lower summer insulation (exposure to the sun's rays) at fifty-five degrees north latitude. Such cooler summers in high latitudes tend to preserve each winter's snowfall, which over thousands of years leads to snow from successive winters inducing growth in the northern ice sheets, evidentially causing the onset of a new ice age.

The Earth may be currently in an ice age because within each major glaciation ice caps and mountain glaciers are oscillating between extension and retreat. The last retreat concluded approximately ten thousand years ago and probably represents only an oscillation, not a final ending. The recent trend toward global warming, however, has reduced fears of any imminent return of an ice age.

Imperialism

Although many governments and political bodies have been labeled “empires” throughout world history, the related term *imperialism* today refers to a set of ideological principles whereby one group sets out to impose its belief systems on another. This imposition is most often political but can also be cultural, religious, economic, or even ecological.

At its core the term *imperialism* is defined by power relationships and the ability of one group to assert some form of power or control over another. Historians who examine imperialism tend to study either one aspect of this power or one concrete example, such as a particular empire or the spread of a particular system. Most commonly, imperialism refers to the particular type of political organization that emerged during the nineteenth century, the “New Imperialism” by which Europe established empires in Africa, Asia, and Oceania (islands of the central and south Pacific).

The major impact of imperialism was the spread of ideas among different peoples, particularly in highly cosmopolitan empires. Empires operate on two key principles: acquisition of wealth, whether in money or in other resources, and the spread of belief systems to other peoples in order to establish unity under one imperial structure. This structure comes with an attendant worldview on religious, social, cultural, and political matters that subjects of the empire are expected to accept or at least accommodate. Internal conflicts within empires usually come as a result of resistance to the imperial worldview by subject peoples. Modern empires built upon these foundations and added more sophisticated bureaucratic structures and

explicit drives for religious conversion, particularly Islam and Christianity. Improved means of transportation, particularly sailing and later steam vessels, and the discovery of the New World added opportunities for overseas expansion and more diverse empires.

Origins (Sixteenth–Eighteenth Centuries)

The discovery of the New World opened up new paths for exploitation on many levels. After the initial pillage of the Mexica (Aztec) and Inca empires by the Spanish conquistadors, silver mines in Bolivia and Mexico gave the Spanish Empire tremendous revenue. This revenue helped finance the wars of the Habsburg (a European ruling house) against European rivals such as the Dutch, English, and Ottoman Turks. Spain was ultimately overextended by these wars, and the Habsburg emperors found such a large empire difficult to manage effectively. Spain’s rivals also set about exploiting the New World and pushed into the Indian Ocean and the Pacific as well. The biological consequences of the conquest were much more profound in the long run than was silver. Old World diseases decimated up to 90 percent of the native population, leading to the importation of African slaves to labor on the new sugar, cotton, and tobacco plantations. New crops, such as maize and the potato, were exported to the Old World, allowing for diversified agriculture and large population growth. This package of crops would also allow Europeans to establish themselves in areas with similar climates, opening up areas of settlement in the Americas, South Africa, and Australia. The increase in population and resources promoted increased

The British statesman William Pitt and Napoleon carve up the world in this caricature by James Gillray, circa 1800. The British Library.

trade as demand went up and new opportunities for trade were opened.

Increasingly, European wars took on a global dimension as conflicts in Europe were fought on the high seas around the world and by small groups of European soldiers and their native proxies in locations as far apart as Canada and India, with the Seven Years' War (1756–1763) being the best example. Settlements were initially seen as less important than trading posts, and they were certainly less lucrative. British, French, and Dutch East India Companies were established and were given extraordinary powers to administer territory, raise armies and fleets, and wage wars to promote and manage trade.

Europeans settled areas that had a climate similar to Europe's and that had few natives to put up resistance (largely due to diseases introduced by Europeans). Such areas were largely seen as a useful outlet for excess or discontented populations in Europe and were given a large degree of autonomy in exchange for sending back resources for the home country. This practice was referred to as "mercantilism" and became a source of discontent in colonies as their economies developed. Until the American Revolution, the British were the major success story of the eighteenth century, supplanting the Dutch as the dominant naval power and winning a series of wars. These victories

gave Britain a dominant position in the Caribbean and North America and made Britain the dominant European power in India.

British involvement in India would be crucial for the development of imperialism in both theory and practice during the nineteenth and twentieth centuries. Previously European empires had been trade oriented, establishing trading posts to facilitate exchange, or colonial, taking advantage of favorable circumstances to transplant populations and essentially replicate themselves abroad. The New Imperialism was a shift in philosophy whereby European powers attempted to impose their political, economic, and cultural systems upon subject peoples.

Britain and India

Britain had become the dominant power in India through a series of wars with both local powers and the French. The British East India Company (EIC) had been chartered to solidify the British trade position in Asia, particularly in the tea trade. Increasingly as a result of military conquests and political maneuvers, the EIC became a governing body over large sections of India, particularly in Bengal, by the end of the eighteenth century. The mission of the company was heavily questioned in the aftermath of corruption scandals that attracted parliamentary investigation.

In 1880 cartoonist Thomas Nast targeted France's objection to American and British imperialist ambitions to control the Panama Canal.

The British government was also under pressure to allow more missionary activity, something resisted by the EIC for fear that such activity would anger the Hindu and Muslim populations in India.

Through the first half of the nineteenth century the EIC expanded its political control over India through conquest and legal seizure of princely states when the heirs died without a successor. By the mid-1800s the British were in control of almost all of India, through either direct rule or "indirect rule" whereby princes retained their states, but the company directed foreign and trade policies. This gradual conquest led to questions over the purpose of British involvement in India. People raised moral questions as the missionary movement wanted to make more attempts at conversion, and some people objected to the increasing exportation of opium grown in India to

China, an exportation that led to the Anglo-Chinese First Opium War (1839–1842). This war dramatically demonstrated the technological superiority of Europeans and helped lead to an important strain of thought in modern imperialism: that technological superiority implies cultural and eventually racial superiority.

The outbreak of the Great Mutiny in India in 1857 led people to reassess the goals of imperialism. The EIC was removed as the governing power, and India was placed under Crown rule. With trade no longer the top priority, the concept of a civilizing mission took over, whereby the British would bring the benefits of their technology, government, and culture to India while still exploiting India's resources. This shift was crucial for the New Imperialism because now the "civilizing" aspects of imperialism would be the prime justification for conquest.

The Scramble for Africa

The slave trade led Europeans to hold a number of concepts about Africans. The first of these concepts was that Africans were an inferior race, thus justifying the practice of slavery. The second was that Africa was an uncivilized "dark continent" waiting for exploration and exploitation. The primary obstacle to greater European penetration of Africa was the tropical disease belt that took a heavy toll on European settlers, traders, and missionaries. Advances in medicine, particularly the discovery of quinine, which gave a resistance to malaria, allowed for greater European activity in central Africa during the 1860s. Dr. David Livingstone was perhaps the most important of the new explorers. Livingstone was a Scottish missionary and explorer, and his accounts of Africa and the search for him conducted by another explorer, Henry Morton Stanley of England, captured the public imagination. Lurid accounts of the slave trade and living conditions in Africa increased calls for intervention.

Although European powers had previously established colonies in north and south Africa, the late nineteenth century brought a remarkably swift conquest of the rest of Africa. The Berlin Conference of

1884–1885 set the precedent for the immanent division of Africa among European powers, with no input from the natives, creating arbitrary divisions with no account for tribal and ethnic groupings. Europeans justified their rule on the basis of the civilizing mission, ending the slave trade and bringing Europe's superior way of life to Africa. The reality was much different because the conquest was marked by significant brutality and exploitation. Natural resources were a major factor as gold, diamonds, ivory, and rubber were extracted, frequently with forced native labor. Resistance was largely futile, although the Italians failed to conquer Ethiopia at the turn of the century (although they would conquer Ethiopia under Fascist leader Benito Mussolini in 1936), and Britain suffered early setbacks in South Africa against the Zulu and the Boers and in the Sudan against the Mahdists.

Ideologies of Imperialism

The Enlightenment (a philosophic movement of the eighteenth century marked by a rejection of traditional social, religious, and political ideas and an emphasis on rationalism) had given the minds of Europe a drive to order things by the use of reason and deduction. Scientific advancement and orderly societies were the measuring posts by which the Europeans ordered the world. Other peoples were encountered and measured by these measuring posts, and imperialism was justified when peoples came up wanting. Bringing the benefits of progress, science, and reason to the benighted people of the Earth was the positive drive of imperialism. In reality, this drive became more of a drive for “God, gold, and glory” at the expense of the people who were told that all was done for their benefit. The economic benefits of imperialism were mixed, with some colonies that had extensive natural resources yielding vast profits but others being financial drains on the home country. Critics of imperialism, such as the English economist John Hobson, saw colonies as an unnecessary financial burden that hindered free trade, whereas Russian Communist leader Vladimir Ilich Lenin saw colonies as the last stage of capitalism before the inevitable worldwide

proletarian revolution that the German political philosopher Karl Marx had predicted. Imperialism was therefore to some extent irrational because informal empires of economic dominance were more logical from a business standpoint than the expense of direct military and political control.

But business and scientific curiosity blended with a romantic sense of adventure, and the general public who followed the accounts of Stanley and Livingstone avidly consumed serial stories and novels with imperial themes. The English writers Rudyard Kipling, H. Rider Haggard, and their counterparts outside Britain gave readers an exciting version of the imperial mission: that even if most people could not take part, readers could feel part of a greater project. Kipling's poem “The White Man's Burden” was aimed at a U.S. audience, calling on people to “send forth the best ye breed” to govern Filipinos “half-devil and half-child” (Kipling 1899). Adventure appealed to men who were increasingly desk bound and out of touch with nature after the emergence of the white-collar middle class after the Industrial Revolution. Imperialism was a chance to reorder the world in a way that made sense, creating a world in which men were active and women were subordinated. However, women also found opportunities to fight for equality, using the treatment of women by colonized peoples as a way of equating women's rights with greater civilization.

The English naturalist Charles Darwin's ideas lent credence to philosophies of competitive social hierarchies that weed out the weak and reward the strong. Social Darwinism justified imperialism by twisting Darwin's theories of adaptation and natural selection to human societies. By this logic European nation-states competed with one another for colonies, and subject peoples were the victims of natural selection, not fit to govern themselves. Some of the more horrific brutalities inflicted in Africa were justified by this logic, leading to massacres and forced labor on a massive scale. Nationalism and race were increasingly blended, and the idea of races as Darwinian species competing with one another took hold, driving Europe to more aggressive militarism before World War I.

The bare-breasted woman in this drawing, harassed and restrained by British statesmen, represents America; the female figure of Britannia stands by, shielding her face with her hand. From *London Magazine* (May 1774).

Anticolonial Movements

Although resistance to imperialism had existed from the beginning, a more articulate version emerged during the twentieth century. People had fought wars against imperialism during the late nineteenth century, but European military superiority made these wars largely futile gestures. Millennial movements (apocalyptic antimodernist religious movements) were in part a reaction to this superiority, with visions of religious faith triumphing over technology, guiding movements among the Sioux in the United States, the Boxers in China, and the Mahdi's jihad (holy war) in the Sudan. Although these movements were failures in the short term, they did lead to moral questions about the imperial mission, and the vast number of natives massacred by European firepower was soon mirrored in the mud of Flanders in northern Europe as a generation of young European men died in the trenches of World War I.

Large numbers of colonial native troops were used by the Allies in World War I, with many serving in France. The horror of war and the squalid conditions that the troops served in led many people to question the supposed superiority of Western society. Movements such as the Indian National Congress had emerged before the war but now took on new urgency. The Indian nationalist Mohandas Gandhi's campaign for Indian self-rule, Hind Suaraj, was based on the perception that although Britain may claim

noble goals, in essence racism defeats these goals. Gandhi's genius lay in passive resistance and the realization that the West's own values could be turned against imperialism. In India and elsewhere claims to self-rule, freedom of expression, and racial equality became stronger as the ideals that Europeans professed took hold.

If World War I rattled the structure of imperialism, World War II was a finishing blow. A war fought against the ultimate form of racial nationalism in the name of freedom led to the overwhelming desire for independence. India was the first to achieve independence, although with traumatic consequences for those people caught on the wrong side in the division between Hindu India and Muslim Pakistan. Similar results and consequences came with decolonization in other parts of the world as tribal, ethnic, and religious tensions reemerged amid frequently bloody struggles for independence against colonial powers. These struggles merged with the Cold War as Communism championed itself as a liberator from the capitalist structure of imperialism. The arbitrary dividing lines of colonies fed civil and national wars in Africa and Asia and led to a sense of bitterness and resentment that is still felt today.

Imperialism and Gender

Attitudes about “appropriate” sexual behaviors of both men and women were central to imperial endeavors beginning in the late 1800s; ideals such as these allowed colonizers to categorize and divide indigenous peoples into distinct and knowable groups. Colonial encounters between rulers and ruled often changed local gender relationships and ideals in ways that deeply affected culture in the colonies and in imperial metropolises.

From the late nineteenth century until the end of World War II, all of the most powerful nations on Earth (along with others that aspired to great power) pursued the strategy of imperialism in an attempt to achieve national political and economic goals. Although imperialism was not new (Great Britain and Spain are notable examples of a countries whose pursuit of empire began centuries earlier), this period is historically unique because so many nations became involved in imperial ventures and because the territories they claimed were so extensive. Between 1885 and 1914 alone European countries added 2.8 billion hectares to their imperial territories, the United States and Japan joined European countries in the pursuit of empire, nearly all of Africa came under colonial domination, and the British Empire grew to include one-quarter of the world’s population.

Societies and systems established by imperial nations varied greatly across time and space. Some became settler colonies, where colonizers would establish large, permanent communities. Others were created because of the resources that could be extracted

or because of their strategic location and were ruled by small numbers of administrators backed by military force, or even by indigenous groups overseen by colonial administrators. Whatever form imperial societies took, they all profoundly affected both rulers and ruled economically, socially, culturally, and politically. Moreover, during the last two decades scholars have begun to understand that imperial systems around the world were maintained and legitimized, at least in part, through the use of language and policies based on gender ideals. These ideals included beliefs about the appropriate behaviors and sexualities of both men and women and were frequently used to mark distinctions between colonizing and indigenous cultures. They were also frequently inseparable from beliefs and attitudes about racial difference and were often used to shore up notions about the inherent inequality of colonized peoples. In addition, colonial encounters between rulers and ruled—varied though they were—changed local gender relationships and ideals in ways that deeply affected culture in the colonies as well as in imperial metropolises. These changes were not uniform in all colonies, or even within the various “national” empires. Rather, they depended on existing indigenous cultures, the presence or absence of natural resources, the presence or absence of colonial settlers, the degree of incorporation into the global economy, access to land, and many other factors. When examined from a global perspective, then, the relationship between imperialism and gender emerges as a complex phenomenon. At the same time, we can also detect several broad similarities that elucidate global connections and patterns.

Gender as a Means of Marking Hierarchy

Beliefs about gender, sexuality, and gender roles were central to imperial endeavors around the world because such beliefs provided legitimation for preserving distinctions between rulers and the ruled and because they helped colonizers categorize—and hence divide—indigenous peoples into distinct and knowable groups. Although the precise form that such beliefs took varied across time and space, the need to clearly mark the boundaries between colonizer and colonized through language and practices associated with gender and gender difference was widely shared across many imperial systems.

Nearly every imperial system sought to justify the unequal distribution of power between rulers and ruled—and even the existence of colonies themselves—by concerning itself with the sexual behaviors, appetites, and attitudes of colonized men and women. One recurring theme in French Indochina, British India, the Dutch East Indies, and British South Africa—to name only a few—was the idea that white women were in constant danger from the voracious and perverse sexual appetites of colonized men. The fear of rape, and the need to protect white women from it, hence came to justify the strict separation between colonizers and colonized as well as the careful control of both colonized men and white women. As a result, white women often found their lives in colonies paradoxically quite comfortable (because of servants, privilege, and leisure time) as well as quite restricted. Colonized men, for their part, were routinely excluded from positions in which they might have even a remote chance of exercising power over white women. They also found themselves at risk of severe punishment if they transgressed the boundary between themselves and colonizing women. Perhaps not surprisingly, rhetoric about the need to control colonized men and to protect white women grew more intense during times of high colonial tension.

One example of the ways in which gender could be employed to maintain distinctions between rulers and ruled was the 1883–1884 Ilbert Bill controversy in British India. The bill had been designed to concede a small amount of power to Indian civil servants by allowing Indian judges jurisdiction over some European cases. However, Britons in India vehemently opposed even the slightest suggestion that Indians might be able to pronounce judgment over Europeans and openly attacked the bill on the grounds that it threatened the safety of white women. Although the bill itself said nothing about women, opponents argued that it opened the door for Indian civil servants—whose ultimate fantasy, they asserted, was the possession of a white woman—to use their new power to take sexual advantage of British women. Moreover, opponents claimed that Indian men could not be expected to treat British women with decency because they were said to treat their own women so poorly. In the end opposition to the bill among the British community in India was so strong that it had to be dropped. Indian men had been kept firmly in a subordinate role through rhetorical claims about the gendered consequences of conceding power to colonized men.

Anxieties about racial mixing—miscegenation—also echoed widely across imperial systems during the last half of the nineteenth century, and here again beliefs about gender and sexuality played critical roles in maintaining the separation between rulers and ruled. Most imperial systems were predicated on the belief that colonizing men needed sex in order to be satisfied. The problem, however, was a shortage of colonizing women in many colonial societies—even those that encouraged settler families. As a result, colonizing men frequently established sexual relations with indigenous women through prostitution, concubinage, or, less commonly, marriage. Such relationships were rarely based on true partnership: even when colonized women entered into them of their own choice (abundant evidence suggests that the use of force and manipulation was quite common), they

enjoyed few rights or privileges and could be discarded at will. Moreover, these sexual relationships produced a whole set of new problems. Chief among these was how to maintain distinctions between colonizers and colonized given the existence of such intimate relationships. Even more problematic was how to classify and treat the mixed-race children who resulted from these relationships.

In the East Indies Dutch efforts to confront these issues illustrate both the centrality of sex management to imperial projects as well as the ways state policies about the regulation of sex could change over time. Prior to the twentieth century the Dutch East Indies Company sharply restricted the immigration of Dutch women to the East Indies. The company reasoned that Dutch men would be more likely to remain in the East Indies if they established long-term relationships with indigenous women. Moreover, indigenous women were less expensive to maintain than European women and could be expected to perform domestic labor in addition to their sexual functions. For these reasons the company advocated that Dutch men keep concubines—women who shared all of the duties of wives without the legal protections and entitlements of marriage. By the 1880s concubinage was the most common domestic arrangement for European men in the Indies, a situation that produced tens of thousands of mixed-race children. Yet, by the turn of the twentieth century, the existence of this large mixed-race population had begun to worry the Dutch East Indies Company and the Dutch government because it threatened to blur the divide between the colonizers and the colonized. To which group did these children belong? Were they Dutch or Indonesian? Would they support Dutch rule, or would they try to subvert it? As part of these worries, Dutch officials increasingly began to argue that Indonesian concubines had neither the skills nor the morals to raise their mixed-race children to be adults worthy of Dutch citizenship. As a result, during the early twentieth century the Dutch government reversed earlier policy by seeking to ban the practice of concubinage and to encourage instead the immigration of Dutch women to the Indies. These women, the

government now believed, would provide a civilizing influence on Dutch men and would have the cultural skills to raise their children to be proper Dutch citizens. For European men who could not afford Dutch wives, the government now encouraged prostitution as a means of side-stepping long-term, family-style liaisons with indigenous women. In both the pre- and post-twentieth-century East Indies, government concerns with the sexuality and sexual behaviors of both men and women, colonizers and colonized, highlight the central importance of sex management—and the gender relationships such management depended upon—to the imperial state.

Beliefs about gender also contributed to imperial policies of divide and rule—that is, policies that emphasized differences between subgroups of colonized peoples as a way of minimizing unified opposition to imperial rule. In places as far-flung as India, Indonesia, South Africa, and French West Africa, to mention only a few, such policies encouraged preferential treatment of certain groups, which tended to pit these groups against less-preferred groups. Moreover, colonizing powers often bestowed favor on groups who seemed to embody colonizers' own notions of ideal masculinity. In French Algeria, for example, French colonial administrators articulated stark divisions between the two major ethnic groups in the region: Kabyles and Arabs. Kabyles, the administrators argued, were superior to Arabs in nearly every way. Kabyles were sedentary rather than nomadic; they lived in mountains rather than the plains; they spoke an Aryan language rather than a Semitic one; and they were secular rather than religious. Gender ideals were also central to Kabyle superiority. The French, for instance, perceived Kabyle men as tall and athletic and likened their bodies to French ideals of the male physique. Kabyles were also said to be brave and fierce warriors who had proven themselves worthy foes of the French. Finally, despite their ferocity, Kabyles were said to treat their women with respect, which again resonated with French notions about themselves. Arabs, on the other hand, were perceived as physically small, lazy, slovenly, and cowardly people who brutally oppressed their women.

The power I exert on the court depends on the power of my arguments, not on my gender. • Sandra Day O'Connor (b. 1930)

These perceptions of gendered difference were neither trivial nor matters of simple representation. Rather, they encouraged preferential treatment for Kabyles, imposed a strict division between two indigenous groups, and deeply influenced French-Arab interactions in Algeria. Indeed, the language of gender difference in imperial situations served not only to maintain distinctions between rulers and ruled, but also to maintain distinctions between different groups of colonized people.

Gender and the Colonial Encounter

Colonial encounters between rulers and ruled had profound social, cultural, political, and economic effects all over the world. In terms of gender, such encounters frequently disrupted local ideologies, relations, and traditions and often led to changes in all three. In virtually every colonial encounter, the gender ideals of the colonizing powers helped to shape colonial practice, law, and culture. However, the way such ideals were translated into policy depended upon the response of colonized peoples, and thus the effect of such ideals was neither uniform nor predictable. Moreover, the disruptive effects of the colonial encounter on gender ideals were not a one-way street because they influenced gender ideals in imperial home countries as well.

Nineteenth-century Hawaii illustrates the ways colonial gender ideals could interact with indigenous gender ideals in unexpected ways. Prior to contact with westerners during the eighteenth century, Hawaiian culture had imposed sexual separation between men and women and had mandated that women follow certain eating taboos. In other respects, however, Hawaiian women played important social, economic, political, and spiritual roles and maintained a large degree of personal autonomy. As Western—especially U.S.—influence increased in Hawaii during the nineteenth century, Hawaiian women were criticized as being sexually immoral, were consistently written out of U.S.-dominated politics, and were increasingly defined as legally subordinate to Hawaiian and U.S. men. Thus, as a result of U.S.

intervention into Hawaiian society, Hawaiian women's legal and social positions deteriorated. Yet, these same interventions also led to an improvement in Hawaiian women's position as landholders during the last half of the nineteenth century. This unexpected improvement was the result of the Great Mahele of 1848, when the Hawaiian government—under duress by U.S. interests—divided Hawaiian land into salable pieces. The overall result for Hawaiians in general was massive dispossession from the land. For Hawaiian women, however, the results were much more ambiguous because the number of women who inherited land in the post-Great Mahele period dramatically increased. In part this increase was a result of indigenous choices and beliefs about women as effective guardians of Hawaiian land. The net effect was the preservation of Hawaiian women's economic and social importance even as their legal status diminished as a result of discriminatory U.S. policies.

Further cases illustrating the interaction of colonial and indigenous gender ideals abound in colonial Africa. In northern Ghana, for example, the implementation of the British judicial system caused indigenous women's legal status to deteriorate. In particular, colonial rule sought to introduce and enforce the notion that wives were the property of their husbands—a notion that, although foreign to Ghanaian gender ideals, allowed men to claim increasing legal control of their wives. In colonial Tanganyika European authorities instituted policies—such as taxation and the conversion of cattle sales to cash—that increasingly defined Masai men as heads of households and allowed them privileged access to the political domain. Masai women, who had long played vital economic and social roles within their communities, were thus increasingly marginalized by colonial policies that clearly favored men as political and economic actors. At the same time African women were not merely passive victims of a patriarchal partnership between colonizers and indigenous males. Rather, African women in many colonial states manipulated colonial court systems for their own benefit, ventured into independent economic enterprises, and moved into new occupations—as

teachers or midwives—opened up to them by the colonial encounter.

Colonial encounters could also shape gender relations in imperial home countries. In Britain imperialism informed the gender identities of both women and men and often provided the context within which claims about appropriate gender roles were made. A case in point was the British feminist movement, which developed and grew during the last half of the nineteenth century—and thus coincided with the massive expansion of the British Empire. British feminists advocated equal legal rights with British men, but they justified their claims to equality by arguing for the need to represent and civilize colonized—especially Indian—women. Indeed, feminists argued that the oppressed condition of Indian women necessitated their own political participation so they could utilize their superior moral authority to “uplift” their Indian “sisters.” In this context British feminists’ sense of themselves as women depended heavily on their perception of gender relations in the wider imperial world.

Gender and the Nationalist Response to Imperialism

Given the centrality of gender ideologies to imperial projects around the world, we should not be surprised that they were similarly central to a variety of nationalist responses to imperialism. Yet, gendered responses to imperialism did not follow set patterns across time or space and varied widely in relation to both the colonial power and local culture. One pattern that did emerge in places as diverse as post-1945 India and Indonesia, 1960s and 1970s Zimbabwe, and 1950s and 1960s Algeria was the formulation of an aggressive, hypermasculine nationalist rhetoric. Where this pattern emerged, colonized women sometimes became targets of nationalist violence. In other cases they were idealized and made to stand as symbols of purity and tradition. Both strategies tended to marginalize women’s roles in nationalist struggles and tended to complicate postimperial gender relations. A second, paradoxical, pattern was the active participation of

Eugene Delacroix, *Greece Expiring on the Ruins of Missolonghi* (1826). Oil on canvas. Western artists traditionally cast women as allegorical personifications of a country or a cause. Musée des Beaux-Arts (Bordeaux).

women in most nationalist movements all over the world. Indeed, women from French Indochina to Jamaica to Angola served in critical roles as messengers, providers, and even as soldiers.

The case of Zimbabwe in Africa illustrates the complex ways gender could help constitute the language and practices of anti-imperial nationalist movements. Under colonial rule Zimbabwean men felt increasingly emasculated as they lost status to white Europeans, were treated as children, and were unable to protect Zimbabwean women from the sexual advances of colonizing men. Emasculation took more material forms as well because colonial rule had made it progressively more difficult for Zimbabwean men to achieve those goals that were thought to mark ideal masculinity—including especially taking a wife, buying land, and providing for a family. As a result,

Zimbabwean nationalism during the 1960s and 1970s took on an aggressively masculine posture (the two main parties styled themselves after the cock and the bull) that emphasized the importance of being manly, virile, and heterosexual. Incidents of violence against women increased dramatically during this period, evidenced by a spike in the number of rapes and attempted rapes. At the same time, women's actual participation in the Zimbabwean nationalist movement was crucial to its eventual success. They provided information to nationalist guerrillas, gave food and shelter to nationalist fighters, and, after 1975, were trained as guerrilla fighters themselves. Yet, in spite of such active women's participation, Zimbabwean independence in 1980 did not lead to equality for Zimbabwean women. Instead, like many other states that emerged in the wake of successful anti-imperial movements, patriarchy was simply reconfigured in new ways—boosted and encouraged by the aggressively masculine ways that many colonized men responded to their colonial overlords.

The Indonesian nationalist movement during the immediate post–World War II period shared the hypermasculine tone of the Zimbabwean nationalist movement. As in Zimbabwe, Indonesian men had long endured denigration by Dutch colonizers, who consistently referred to Indonesian—and especially Javanese—men as weak and effeminate. Moreover, Dutch men had gained privileged access to Indonesian women. To combat this sense of emasculation, Indonesian nationalists in the anticolonial war of 1945–1949 consciously adopted an aggressively masculine ethos by celebrating toughness, virility, and militarism and broke with established (Javanese) cultural traditions of courtesy and gentleness. In this revolutionary movement, women and female sexuality were seen as dangerous and even traitorous. Women's colonial roles as concubines (*nyais*) had made them suspect as potential spies, and weakness associated with women was viewed as a potential drain on, and distraction from, the cause of revolution. Indeed, because so many Indonesian nationalists felt it necessary to fight European imperialism with a new, hypermasculine gender identity, the movement turned

against its female supporters in a bid to create a new sense of masculinity on the European model.

Implications

The relationship between global imperialism and gender was complex. It was not uniform across space and time, and its precise form varied widely according to local conditions, the colonial culture being imposed, and the specific issues involved. Moreover, the consequences of gender ideals in imperial situations often worked themselves out in unintended, ambiguous, and unexpected ways. What is clear, however, is that beliefs about gender were central to imperial projects around the world and that they had real, observable effects in the material world as well as in the realm of representation, discourse, and psychology. In addition, gendered responses to imperial control played a role in shaping gender relations in many newly independent nations, with effects that can still be felt in the present.

Inca Empire

About a hundred years before the Spanish conquistador Francisco Pizarro took the capital of Cuzco in 1533, the Inca ruled a vast empire that rivaled only China's. Through diplomacy and force, the Incas conquered diverse ethnic groups with different beliefs and social structures. During the first fifty years of Spanish rule, epidemics, civil wars, and forced labor wiped out over half of the population.

By the middle of the fifteenth century CE, the Inca Empire was the largest pre-Hispanic state ever known in the Americas. The empire covered almost a million square kilometers and stretched over the Andes for more than 4,000 kilometers. Running in a band from what is now the northern border of Ecuador to the Chilean capital of Santiago, the realm encompassed coastal deserts, rugged mountains, and verdant forests. From the imperial capital of Cuzco (located southeast of present-day Lima, Peru), the emperor, known as the Sapa Inca (Unique Inca), held sway over 10 million subjects from myriad ethnic groups that spoke different languages, followed different subsistence strategies, supported different political structures, and worshipped different gods.

The Incas called their empire Tawantinsuyu, “the land of the inextricably linked four quarters.” The four quarters, Collasuyo, Antisuyo, Cuntisuyo, and Chinchasuyo, were political provinces defined by imaginary lines emanating from the capital. The name Tawantinsuyu reflected more a desire than a reality—the union of these quarters, and the people that lived within them, remained tenuous throughout the state's short life span. When the empire was

about one hundred years old, a band of 168 Spanish adventurers led by Francisco Pizarro (c. 1475–1541) helped bring an end to Tawantinsuyu in 1533. Since there was no indigenous system of writing in the Andes, our understanding of the empire is gleaned from archaeology, early Spanish documents, and a handful of native accounts. These sources often disagree, and there remain many gaps in our understanding of Inca life.

The Rise and Fall of an Empire

According to their oral histories, the Inca civilization began when four brothers and four sisters emerged from a cave at the site of Pacariqtambo (The Inn of Dawn) near Cuzco. The siblings, led by Manco Capac and his sister/wife Mama Oqlla, went on a quest to find a place to settle. At the end of this search, Manco Capac founded Cuzco and became the first Inca king. The Incas were just one of many small, warring, ethnic groups that populated the mountains of central Peru until the beginning decades of the fifteenth century. At this time, the eighth ruler, Viracocha Inca, was preparing to give the throne to one of his sons. Before a transfer of power could occur, a rival group, the Chancas, invaded and surrounded the village of Cuzco.

Viracocha Inca and his heir fled the city, and another son, Cusi Inca Yupanqui, was left to defend Cuzco against overwhelming odds. As he and the forces under his command awaited certain death at the hands of the Chanca, Cusi Inca Yupanqui had a vision. The creator god told him that if he spread the true religion, he would be a great ruler and conqueror. Inspired by his vision, Cusi Inca Yupanqui broke the siege and

This eighteenth-century engraving shows Francisco Pizarro capturing the Inca leader Atahualpa in 1532.

then went on to rout the Chanca. He was crowned ruler and took on the name of Pachakuti—"Cataclysm" or "He Who Remakes the World." Over the space of fifty years, Pachakuti (reigned 1438–1471) and his son Tupac Yupanqui (reigned 1471–1493) conquered almost all of what would become the Inca Empire. The remaining portions of the empire, Ecuador and the chiefdom of Chachapoyas in northern Peru, were captured by the succeeding king, Huayna Capac (reigned 1493–1526).

The Incas legitimized their expansion as a means to spread the true religion. The true religion entailed two things—reshuffling existing gods and practices to fit within a "proper" imperial pantheon and the placing of the Inca sun god, Inti, at the second position in that hierarchy (Viracocha, the creator god, held the highest position). As long as a conquered group agreed to both acquiesce to the god's position in this hierarchy and worship Inti, local religions could remain intact. In this way, the Inca were able to fulfill their divine mandate for expansion without seriously challenging local beliefs.

The Incas conquered through a mixture of diplomacy and force. Resisting the empire often had terrible consequences; after defeating the Collas of the Lake Titicaca Basin, for example, the Sapa Inca destroyed many villages, killed many of the inhabitants, and cut off the heads of all of the Colla lords. Those that acquiesced to Inca rule, however, were offered sumptuous gifts and given a privileged position in the new imperial hierarchy.

By the end of Huayna Capac's reign, the strain of keeping the massive empire together was beginning to show. The Sapa Inca was faced with unrest along both the northern and southern frontiers of the empire. Rebellions within the realm, although a problem throughout the empire's existence, may have become more frequent. The groups that populated the semitropical forests along much of the regime's eastern border were nuisances that proved impossible to defeat for a number of reasons. They were small, mobile, and politically acephalous. Inca military tactics did not work well in tropical forests, and tropical peoples often used guerrilla tactics and did not mass their troops. There were the risks of disease, especially Chagas disease, a parasitic infection. There was also little of value obtained in the Inca's expeditions into the eastern lowlands. The exotic animals, honey, feathers, and a bit of gold that they captured were not worth the effort. Huayna Capac's swift death, by an epidemic of smallpox that preceded the Spanish invaders, accelerated civil unrest and caused a war of succession between his two sons, Huascar and Atahualpa (c.1502–1533). Atahualpa finally defeated his brother, but this event was overshadowed a few days later by Atahualpa's capture on 16 November 1532 by Pizarro. By the following November, Atahualpa and Huascar were dead and the Spaniards controlled Cuzco. In 1572, the last vestiges of Inca resistance ended with the capture of the jungle redoubt of Vilcabamba.

At the time of the Inca conquest, it appears that the empire was overextended. By the reign of Huayna Capac, the pace of imperial expansion had significantly slowed and the emperor spent much of his time quelling rebellions in different parts of the empire. This

strain in keeping the empire together, as mentioned above, increased with the wars of succession between Huascar and Atahualpa. Huascar was the designated successor to Huayna Capac and was supported by the royal lineages in Cuzco. Atahualpa, who controlled the bulk of the seasoned army in Quito, at first acknowledged Huascar as the rightful heir but refused to visit his half-brother (different mothers) in Cuzco. Huascar suspected treason (perhaps rightfully so, it does appear that Atahualpa was making plans to stake his claim to the throne) and began the war of succession by sending an immense but undisciplined force in a failed attempt to capture Quito. For the next six years, there were a number of battles and diplomatic overtures between the forces of the brothers with little concrete results. Finally, Huascar was captured in battle when a small contingent of soldiers led the emperor into a trap. Atahualpa was in the midst of his triumphant march to take over Cuzco when Pizarro captured him.

While the Inca account of the later years of the empire may be largely accurate, archaeological evidence contradicts aspects of their rise to power. For example, research suggests that the Incas were important regional players who controlled many valleys around Cuzco during the preceding Late Intermediate Period (1000–1438). While the Chancas attack may have occurred, the Incas possessed a powerful state when the attack occurred. In another example, recent radiocarbon dates place the expansion of the empire twenty-five to fifty years earlier than the dates provided by written sources.

The Heartland

When the Spaniards entered Cuzco in 1533, the capital housed more than 100,000 people and was the largest city in South America. The city, located in the same place as modern Cuzco, stood in a fertile mountain valley in central Peru at an elevation of 3,395 meters. At the time of the Inca expansion, Cuzco was probably a typical mountain town of thatched huts that contained several ethnic groups living in distinct districts. Around 1463, Pachakuti returned

Inca builders fit together massive fine-cut stone blocks, like the ones used to build this wall in Cuzco, without the use of mortar. Library of Congress.

to the village from his conquests and removed all non-Inca ethnic groups from the city's core and resettled the groups into fringe enclaves. The Sapa Inca then rebuilt Cuzco as his capital.

The city's center was divided into upper and lower sectors that abutted a large plaza divided into two parts. In the middle of the plaza, a pointed stone covered in gold was the focal point for many state ceremonies. The large halls surrounding these plazas were likely temples, palaces, and houses for women who served the emperor. The city core may have been shaped in the form of a puma, with the megalithic terraces of Sacsawaman forming its head. Builders fitted together the massive fine-cut stone blocks used in Sacsawaman without the use of mortar. This type of masonry was used in many of the important buildings of Cuzco; architectural embellishments included trapezoidal niches and double (and even triple) jamb doors. Most Inca buildings in both the heartland and the provinces, however, were made of fieldstones or mud bricks (or both).

Crowned from among the members of at least ten royal kin groups (called *panacas*), the Inca emperor was an absolute ruler. The Sapa Inca was divine—the descendent of the creator god Viracocha, and the son of the sun god Inti. When the emperor died, all of his possessions were kept by his descendents. His

mummy was worshipped and continued to eat (via burnt offerings), visit friends (other mummies), and attend ceremonies. This system made it necessary for each successive ruler to build his own palaces, estates, and terraced fields. Through split inheritance, a new *panaca* was formed each time a new emperor was crowned. The *panaca* of the previous emperor maintained his holdings, but each new emperor needed to build his own estates because his new *panaca* had no previous holdings. Royal estates, usually made up of agricultural lands surrounding a cluster of well-made residences, halls, and shrines, controlled much of the land around Cuzco. Machu Picchu, the well-preserved ridgetop site located by Hiram Bingham in 1911, was perhaps one of the estates built by Pachakuti.

Besides the creator and the sun, the Inca pantheon included gods that symbolized other celestial bodies and forces of nature, such as the moon, lightning, thunder, and the rainbow. The Incas also worshipped several hundred sacred sites—often springs, rocks, lakes, and mountains—that were called *huacas*, as well as ancestor mummies housed in aboveground sepulchers. Supplicants offered gold, silver, cloth, ceramics, corn beer, llamas, alpacas, and, more rarely, humans to these divine beings, and many rituals were tied into a sacred calendar of twelve lunar months.

Around Cuzco, the *huacas* were organized on a network of forty or forty-one lines radiating from the Coricancha, Cuzco's sun temple. Called the *ceque* system, each line was assigned to a particular social group that was responsible for the ceremonies at each *huaca*.

The Provinces

There were at least eighty provinces divided among the four quarters of Tawantinsuyu. While ethnic Incas usually controlled the most important political and religious positions in these provinces, local lords retained a significant degree of control over local affairs. In general, the Inca encouraged a degree of autonomy to decrease administrative costs and hinder groups from uniting, and strove to maintain local religions, dress, and languages. Nonetheless, the empire was still a disruptive force. The empire claimed ownership over all natural resources, divided land into tracts for the Incas, the state religion, and the local communities, bought colonists, called *mitmaq-kuna*, into new areas, and moved settlements into more productive growing areas. In addition, the empire tore down or built up political systems according to its interests and organized local populations into units of one hundred, five hundred, a thousand, five thousand, and ten thousand households to facilitate census taking and labor recruitment.

The Inca economic system was neither a market nor a tribute system. No coinage was used in the realm, and, strictly speaking, the empire demanded no goods in kind from its subjects. Instead, the mainstay of the imperial economy was a labor tax that was couched in an ethos of reciprocity. Every household was required to provide some kind of service, such as farming, herding, construction, mining, or military service, to the state. In return, the state sponsored large feasts for its subjects at which enormous amounts of food and drink were consumed. The state also maintained a number of specialists that worked full-time for the state, such as artists, household servants, and temple workers.

The most famous of these specialists were the *aql-lakuna*, young women who brewed corn beer and wove cloth at state centers. Kept under close guard, the Sapa Inca often married these women to Inca and local elites in order to strengthen his political power.

The Incas built provincial administrative centers across the empire. These centers served as local hubs for administration, religious ceremonies, military actions, and labor recruitment. Most importantly, the Inca accumulated the fruits of the labor tax at these sites. The largest of these centers, such as Willkawayman, Pumpu, Cajamarca, and Huánuco Pampo, contained hundreds of storehouses. *Quipus*, mnemonic devices made by hanging knotted strings from a main cord, were used to record the contents of the storehouses. Census data, ritual calendars, astronomical observations, and even histories may have also been recorded on the *quipus*. While many products were consumed locally at the provincial centers, caravans of humans and llamas transported many of the goods across the 30,000 kilometers of Inca roads. The roads, an engineering marvel in the rugged terrain of the Andes, also served to facilitate the movement of troops. A system of runners allowed messages and small items to be carried quickly on these roads over long distances.

The Incas and the World

The opportunity to learn from the Incas was almost completely squandered after the Spanish conquest. The Spanish success, helped by the Inca war of succession, the willingness of subjected groups to rebel, and, most importantly, the diseases that the adventurers carried with them, nearly obliterated Andean civilization. Epidemics, civil wars, and forced labor over the first fifty years of Spanish rule wiped out over half of the population. Entire villages were abandoned, languages were lost, and rituals forgotten. Outside of the Andes, the most lasting legacy of the encounter between the Incas and the Spanish may be the potato.

The daily fare of Inca commoners and elites, the potato has now become an important staple crop in countries around the world. It is an unlikely reminder of a mighty empire that lived for only a short time.

Indigenous Peoples

Although *indigenous* is often used to describe humans (or nonhuman life) with origins in a specific place, the term *indigenous peoples* specifically refers to those who have become minorities in their own lands. Contributing factors include the shift from foraging to agriculture as well as invasion, displacement, and colonization. In the twenty-first century many peoples have “lost” their indigenous distinction by fighting against colonial powers and becoming citizens of independent nation-states.

All peoples are in a sense indigenous peoples, since they come from somewhere. The term *indigenous peoples* has come to refer to those people who have become minorities within their own territories as a result of the expansion of technologically more advanced peoples. The process of creating indigenous peoples accelerated in the past five centuries, though it is a process as old as the advent of agricultural societies. In the twenty-first century, the major groups of indigenous peoples are the Amerindians of the Americas, the Aborigines of Australia and Oceania (including peoples in Papua New Guinea, New Zealand, and Hawaii), the Eskimo and Siberian peoples in the far Northern Hemisphere, the Taiwanese, and the Ainu in Japan. Also, Tibetan and Turkic peoples in China can be considered indigenous peoples.

Although the diversity of indigenous peoples is extremely large—from tiny groups in the tropical Amazon, millions in highland Guatemala, thousands on Pacific islands, to small villages on the tundra—they all share similar characteristics. The similarities are important; in most cases these groups

have been displaced over the past centuries from their original territory or other peoples have moved in and conquered the aboriginal inhabitants. Indigenous peoples by definition do not have separate states, though they may define themselves as “nations” (in many areas such as Canada indigenous peoples are formally known as “First Nations”); in fact they have considerable autonomy, as is the case with the Inuit in Canada. Indigenous peoples also change status as regions are decolonized, and thus become citizens of nation-states where they are the majority and wield most political power.

Historical Periods

In a sense, the conquest of aboriginal peoples goes back before the dawn of history; it might, for example, explain the disappearance of Neanderthal man. There are four principal periods in the history of indigenous peoples throughout the world. The first period chronicles the slowly progressing domination over indigenous peoples through conquest and colonization. This process began with the formation of agricultural societies and the creation of the first states, about 7,000 to 8,000 years ago. Agricultural societies, because their populations quickly outgrew foraging and nomadic societies, replaced these indigenous peoples at a relatively constant pace. At times, nomadic peoples invaded agricultural societies but were eventually absorbed, for example in the Aryan invasions of India in the 1200s BCE or the Mongol invasions of Russia, the Middle East, and China in the 1200s CE.

The process accelerated considerably in the 1500s with the conquest of the Americas and the Philippines

by the Spanish and the Portuguese, beginning the second phase in the creation and subjection of indigenous peoples. The people who would be known as “Indians,” such as the Maya, Mexicas (Aztecs), and Incas, were in the majority agriculturalists as well, thus changing the older dynamic of mostly agrarian versus foraging societies. The Amerindians suffered a process of conquest and absorption by European states and their successors that only ended in the twentieth century. The term *Indian* is of course a misnomer; Christopher Columbus thought he had reached India and therefore called the inhabitants *indios*. Indigenous peoples, who were very diverse, accepted their new name after the Spanish set up legislation favoring Indians a generation after the conquest.

The third phase began in the late eighteenth century, when European powers conquered the peoples of the Pacific islands and Australia; it accelerated in the nineteenth century when western European countries divided up Africa and parts of Asia. In this phase, industrialized societies conquered agriculturalists and foragers, making them indigenous.

The last phase, in which some indigenous peoples ceased to be considered as such, began in the mid-twentieth century as indigenous peoples fought against the colonial powers and were able to create independent nation-states in Africa, Asia, and Oceania. The process continued into the 1990s as the fall of the Soviet Union and the creation of independent nations in its stead converted indigenous groups into national societies. Likewise, indigenous groups within nation-states such as the Americas and the Pacific islands have organized and gained increasing autonomy and political power where societies have become more democratic and accepted their pluriethnic character.

The Making of Native Americans

The expansion of western Europeans into the rest of the world, beginning in the 1450s CE, brought on the most intense period in which indigenous peoples were “created.” Policies toward conquered

In this photo from the early twentieth century, an Aymara Native American in Bolivia poses in traditional dress.

peoples by the major European colonial powers varied significantly, though in all cases the Europeans took away lands, exploited labor, and severely punished those who rebelled. Interactions also varied according to the types of indigenous societies. For example, the Spanish found small-scale societies in the Caribbean in the sixteenth century difficult to subdue. Later, Hernán Cortés and Francisco Pizarro led small groups of Spanish into the Mexica (Aztec) and Inca empires, respectively, conquering them in alliance with dissident indigenous groups. The groups in Brazil were too loosely organized for the relatively weak Portuguese to conquer all at once. Likewise, on the eastern seaboard of North America, the English settlers found themselves in the seventeenth century confronted with loosely federated but militarily powerful peoples who could not be easily subdued.

It took European diseases and many decades for the Portuguese and English to dominate aboriginal

Indigenous peoples often struggle to retain maintain their culture, language, and way of life. This barrier keeps outsiders away from the kiva, an underground religious chamber at the Taos Pueblo, New Mexico.

peoples in their colonies. Thereafter, the Spanish attempted to maintain some land and legal rights for the Indians while regulating the exploitation of their labor, whereas the Portuguese settlers (especially around São Paulo, Brazil) were more interested in enslaving indigenous peoples to work on sugar plantations in the northeast. The English found little use for the indigenous and took away their lands, while the small number of French clustered in northern and central parts of North America allied themselves with powerful indigenous groups as a means of gaining access to the fur trade.

“Becoming” Indigenous in Central Asia and the Pacific

The seventeenth century also saw the subjugation of peoples in Siberia by the Russians. The Buryats were Mongol pastoralists who came under the rule of Russian traders as the Russian state pushed eastward, across the Ural Mountains. The Russians also gained tenuous control over other groups such as the Tuvans, Kalmyks, Kazakhs, and Tajiks because they were better organized and had access to more sophisticated weapons than the natives. In a similar pattern, the Han Chinese, especially during the Qing dynasty (1644–1911/12) extended their control westward, subjugating some of the same Mongol and Turkish peoples in what is today the Xinjiang region

of northwestern China; ironically, the Qing emperors themselves were non-Han Manchurians.

In the eighteenth century it was the turn of the peoples in the Pacific to “become” indigenous: the Muslim and Buddhist peoples of Java and the other main islands of the Indonesian archipelago slowly dominated peoples from islands toward the east, and the British took over Australia and New Zealand. The Australian colony, founded in the mid-eighteenth century as Botany Bay, mistreated the foraging Australian Aborigines by occupying their land and often killing them. The British competed with the French for New Zealand. The native peoples, called Maori, were better organized and, with access to muskets, were able to resist. The British signed the Treaty of Waitangi in 1840 with many Maori chiefs, converting the Maori into British subjects. The Maori conception of land tenure was different from that of the English; as the Maori understood it, selling their land meant being paid for its temporary use rather than its permanent loss. As European settlers began to overwhelm New Zealand, the Maori rebelled in a series of failed wars in the 1860s. Thereafter, the British acquired lands with impunity.

In the Japanese archipelago, the far northern island of Hokkaido is populated by a people called Ainu, who are ethnically distinct. As the Japanese state expanded, it gained control over this population by the fourteenth century CE. During the Edo or Tokugawa period (1600/1603–1868), the state favored the

Japanese over the Ainu. After the Meiji Restoration in 1868, in the name of progress and because of population pressures, the state sent Japanese to relocate in Hokkaido, turning the Ainu into a minority in their own lands. The Ainu were forced to learn Japanese and abandon their customs, though many families continued to maintain their culture clandestinely.

Nation-States and Indigenous Americans

By the early nineteenth century, most of the former European colonies in North America had become independent, but the situation of indigenous peoples worsened uniformly. In North America, the United States and Canada killed the Indians or forced them into reservations on economically marginal lands. In nineteenth-century Brazil, the imperial government saw Indians as people who had to be absorbed into society or exterminated if they opposed assimilation. In the former Spanish colonies, Indians were initially given citizenship rights after independence, but these were later taken away as the elites, mainly descendants of Europeans, fortified the state and adopted scientific racism and social Darwinism as justifications for the usurpations. As a result, indigenous peoples became impoverished during the nineteenth and early twentieth centuries. Also, in the late nineteenth century the national states invaded the frontier territories of indigenous groups not yet under their domination, such as the Pampas and Patagonia in Argentina.

Central Asian Indigenous in the 1900s

Most people defined as indigenous in Asia come from its central parts. Their experience in the twentieth century, with few exceptions, was a horrific one. The Stalinist regime in the Soviet Union, although it paid lip service to ethnic minority rights, was murderous in its policies. The Buryats, for example, tried to establish a Mongolian republic independent of both Russia and China in the early twentieth century. When Stalin incorporated the Buryat region into the Soviet Union, many independence leaders fled. Stalin

demanded their return, however, and when they came back had them summarily executed in 1929. Stalin's actions halved the Buryat population. The Tuva also resisted collectivization in the 1930s, but the Terror of 1937 led to the murder of Tuva nationalists. Despite the declaration of the Tuva region as an autonomous province in 1944, the remaining Tuva were put into boarding schools and "Russianized," while Stalin encouraged Russian colonists to settle there.

The fall of the Soviet Union in 1989 improved somewhat the political situation of some of the indigenous peoples of Siberia and Central Asia. In Central Asia, some of the previously indigenous people transformed into national groups, such as in Kazakhstan, Kyrgyzstan, Tajikistan, and Uzbekistan. Unfortunately, many of these new nations are still ruled by autocrats, limiting rights of all residents.

The Chinese Communist state instituted policies similar to those of Soviet Union in Xianjiang after 1949 and in Tibet after the 1950 invasion. The process of sinicizing the western borders of China accelerated in the last few decades of the twentieth century as increasing prosperity and overpopulation in the eastern sections brought more Han Chinese westward.

Indigenous Movements from the 1980s Onward

Indigenous movements have existed since the advent of nation-states, from the eighteenth century onward, though most movements expressed their demands mainly through violence because of their members' subordination and inability to have a voice in the national political arena. Only in the last few decades has that changed, as governments have provided formal avenues for their citizens to express their discontent. The concept of class as a means of organizing people faded with the decline of Marxism, and thus ethnicity has taken its place in many states where indigenous peoples are prominent, either in the number of people or the territory that they inhabit.

Since the last few decades of the twentieth century important indigenous peoples movements have

flourished throughout the world, from Latin America to Asia, Africa to Europe. All are diverse and have different aims, although many movements were inspired by the passage in 1989 of the International Labor Organization (ILO) Convention 169, which provided indigenous peoples the right to maintain their culture, their language, and their way of life as a part of international law. This passage was made possible by the rise of nongovernmental organizations (NGOs) that have helped to organize and finance these movements.

Failures in Asia

In Asia indigenous peoples movements have not had much success. True, much of the southern portion of the Soviet Union in Asia has become independent, and native peoples have gained control over the government. Independence had little to do with indigenous movements, however; in fact, former members of Soviet political organizations control the newly independent states of Uzbekistan, Kazakhstan, Kyrgyzstan, Turkmenistan, and Tajikistan. At best, indigenous peoples in Asia have been recognized, and governments at times have been willing to accede to indigenous peoples' demands. These developments occurred in Japan, where the native Ainu population of the northern island of Hokkaido in the 1980s and 1990s received recognition of their rights to existence and some economic aid. At worst the Chinese government continues to repress the native populations of the western territories, suppressing any indigenous movement as subversive.

The Chinese case merits special attention. The Uygurs of the Xinjiang Uygur Autonomous Region in northwestern China had briefly established the Republic of East Turkistan in the twentieth century, but the Chinese government quickly crushed it. During the 1990s, the Uygurs again launched a movement for autonomy. The Chinese Communist government responded by building roads and infrastructure to promote economic growth. The government also repressed the autonomy movement and severely restricted the practice of Islam and other Uygur cultural

practices. Lastly, the government flooded the region with Han Chinese to build a non-Uygur majority that could control the resistant natives. This tactic appears to have been effective, and the Chinese have used similar tactics in Tibet as well. Although the Chinese case represents the repressive extreme, other indigenous populations (even ethnic minorities in the former Asian Soviet republics) are generally repressed and have been unable to develop effective movements for greater autonomy. The Chinese state has defined any resistance by ethnic minorities after the events of September 11 as "terrorism," thus providing for a police or even military response. The 2009 riots in the capital Uygur capital of Urumqi, for example, led to widespread repression.

More Success in the Americas

The case of the Americas is more positive for indigenous peoples, although great variation exists there as well. For example, indigenous peoples movements such as the American Indian Movement (AIM) in the United States attempted during the 1970s to force the U.S. government to honor the treaties it signed with Native American tribes during the nineteenth century, but this attempt led to repression by the Federal Bureau of Investigation (FBI) and an infamous standoff between the government and AIM activists at Wounded Knee, South Dakota, in 1973. Since then the movement has been unable to make much headway. After a 1991 law made gambling legal on reservations, many tribes have tried to develop their reservation economies by operating casinos rather than unifying in a single movement.

Other indigenous movements, especially the movement to establish autonomous zones for the Inuit (commonly called "Eskimo") in Canada, have been more successful. Since 1975 the Canadian government has signed a series of laws creating large autonomous territories in the far northern portion of the country. Largest is the territory of Nunavut, where the Inuit have substantial control over legislation and judicial systems autonomous of the Canadian federal government.

A people without history is like wind on the buffalo grass. • **Sioux Proverb**

Farther south indigenous movements have had success in varying degrees. In Mexico, beginning in 1994 the armed Zapatista movement in Chiapas in the southern region brought the indigenous movement back into the limelight, but, in fact, indigenous peoples have not benefited much. In Guatemala an indigenous activist, Rigoberta Menchú, won the Nobel Peace Prize in 1992. Death squads and a violent political climate forced the Maya to organize mainly in Mayan language and cultural organizations without overt political goals. Menchú's example was more important for providing moral authority to movements elsewhere in Latin America.

Indigenous movements initially were most successful in South America in the Andes, where a large indigenous population has been able to mobilize politically. Ecuadorean indigenous peoples after the late 1980s were able to unify the highland peasant communities with the lowland hunters and gatherers. In the highlands issues such as good agricultural prices, access to transportation, and lack of arable land were most important to the indigenous peoples, whereas in the lowlands settler invasions, environmental destruction by oil companies and miners, and indiscriminate road building were the most important issues. Nevertheless, the rather diverse groups were able to organize the Confederation of Indigenous Nationalities of Ecuador (CONAIE) and stage peaceful but massive invasions of Ecuador's capital city, Quito, various times in the 1990s. After that CONAIE formed a political party, Pachakutik, and helped defeat the president of Ecuador in January 2000. Despite Pachakutik's help in 2003 to elect Lucio Gutiérrez, an Ecuadorean army colonel who had conspired with the indigenous peoples in 2000, Pachakutik soon thereafter went into opposition because Gutiérrez was unwilling to fulfill the indigenous peoples' demands. Since then, the government under leftist Rafael Correa has co-opted the issues of Pachakutik and the party lost its political significance.

In Bolivia indigenous organizations remained important, with some ups and downs, to the early twenty-first century. Although indigenous political parties never won many votes, they have allied themselves

with other leftist parties. Evo Morales, during the 2002 elections, "discovered" his indigenous heritage and used it to help oust one president and to get himself elected with a majority vote in 2005. Since then, the government has put into place pro-indigenous policies and made most indigenous leaders beholden to the state. In Peru the indigenous peoples' movement is incipient and relatively ineffective despite the fact that Alejandro Toledo played up his indigenous heritage to win as president in 2001. The massacre by police of indigenous activists in the eastern Peruvian jungle in 2009 led to a revisiting of mining and land policies, but it is unclear whether this will lead to greater influence by indigenous peoples.

Indigenous peoples' movements are less developed in the rest of South America, although the Mapuche in Chile have a relatively strong political presence in the southern part of the country. In Brazil different indigenous groups, in conjunction with NGOs, have been able to protect some of their lands. The smaller numbers of indigenous people, however—compared with the rest of the population in these countries and in the rest of South America—have lessened their political impact nationally. Still, democracy and the abundance of multinational NGOs with their networks and funds have made indigenous movements in South America a force to be reckoned with.

Ethnic Confusion in Africa

Indigenous peoples' movements have cropped up in Africa, but the situation is confused there because conflicts between ethnic groups usually have gone on for many centuries. The major conflicts are between Arabic-speaking peoples and non-Arabic-speaking peoples in the northern tier of the continent and between Bantu-speaking peoples and the indigenous San (Bushmen) people. The San have formed multinational organizations that span South Africa, Botswana, Namibia, Zambia, and Zimbabwe. Each country has a movement and then they have an umbrella movement that spans all the countries where the San live. Such organizations are attractive to multinational NGOs, but the lower San population,

compared with the non-San populations, and the weak national political presence have made the San movements relatively toothless in any one country.

National Status in the Pacific Basin

As decolonization proceeded in the Pacific Basin, ethnic movements (which can be equated to national movements on many islands) gained national status. The only exceptions were the French and U.S. possessions, as well as New Zealand and Australia, with majority populations whose ancestors had migrated from western Europe. In New Zealand the Maori had gained considerable autonomy and political power (they also constituted by 2001 about 15 percent of the population) and were represented separately in Parliament according to their relative population. In 1980 New Zealand established the Waitangi Tribunal to examine land claims dating from the nineteenth century onward. In 1995 Great Britain's Queen Elizabeth apologized publicly for the wrongs committed against the Maori, providing a moral victory for the indigenous population.

In Australia the Aboriginal peoples, although they have gained some rights, lag behind in political organization and in their rights. Aborigines tend to be more rural and less educated than the Maori. It is not clear whether the policies instituted in by former president John Howard in 2004, in which Aborigines are paid for sending their children to school, is a new form of paternalism or is one of "mutual obligation" for all the wrongs committed by whites since their conquest of the continent.

The Future of Indigenous Peoples Movements

In certain regions, such as the Americas, indigenous peoples movements will continue to exist, though in the cases of Ecuador, Bolivia, and to a lesser degree in Argentina, new, leftist governments have subsumed some movements. In Peru and Guatemala indigenous peoples movements likely will begin to

flex their political muscles as democracy, the ability to communicate via the Internet, and NGOs foster organization.

Indigenous peoples movements are not always positive, however. During the 1990s, in countries such as Rwanda, Turkmenistan, and Zimbabwe, rulers at times persecuted people who were seen as settlers in the name of recouping indigenous rights.

Scholars have labeled the mid-to-late-eighteenth-century change in England, France, and the United States—from an agricultural-based society to one focused on the production of goods in factories—as the first Industrial Revolution. Although they disagree whether the development of steam power was its predominant cause, they do agree that industrialization and growing urban populations placed undue demands on fossil energy sources and natural resources.

The Industrial Revolution marked the shift from agriculture-based economy and the production of goods in homes to the production of goods in factories; it corresponded with the growth of population centers and transportation networks for the distribution of those goods. The first Industrial Revolution occurred in eighteenth-century England. Economists generally assign a starting date between 1740 and 1780. Scholars disagree about whether the Industrial Revolution was truly a sudden development or rather the result of changes that had been accumulating for centuries. Similarly, they disagree on the extent to which the Industrial Revolution was a consequence of the development of the steam engine as a source of power. But from the standpoint of the environment, the significance of the Industrial Revolution was the increased use of fossil energy sources and other natural resources, placing ever-increasing demands on the environment. The increased use of resources resulted not only from the energy needs of manufacturing itself, but also from the higher population densities that industrialized regions could support as well as the need to transport workers to the workplace and manufactured goods to market.

Preconditions for the Industrial Revolution

The Industrial Revolution could not have occurred until the “agricultural revolution” had gotten underway in England, making it possible to produce increased amounts of food using fewer workers. The agricultural revolution had a number of causes, including the enclosure of grazing lands, the invention of the seed drill and improved plows, and a more productive system of crop rotation. The potato, imported from the Americas, produced a higher yield of food per acre than cereal grains.

Industrialization in its turn had positive effects on agriculture and the economy. Inventions such as the spinning jenny and the cotton gin increased the profit that could be gained by planting cotton. The mechanical reaper increased the speed with which crops could be harvested. The development of machine tools made the manufacture of farm implements easier. Canals and railroads facilitated the transport of food into urban areas and brought manufactured goods to local markets.

Also necessary for industrialization were a stable currency and banking system. Industrial workers needed to be confident that the coins or banknotes with which they would be paid would be generally accepted in exchange for goods and services. Industrialists often needed to borrow the funds to build and equip factories. Banks and other lenders needed to be sure that the currency in which they would be repaid would have the same buying power as at the time it was borrowed.

Also contributing to the Industrial Revolution were the earlier scientific revolution, associated with English physicist and mathematician Sir Isaac Newton,

James Watt improved on earlier versions of the steam engine by introducing a second cylinder.

and religious thought of the Protestant Reformation, which established a positive correlation between material prosperity and divine favor.

The Coal Industry and the Steam Engine

A case can be made that the precipitating event of the Industrial Revolution was a change in the ecology of England—the depletion of English forestland resulting from the burning of wood for warmth and cooking and its use in construction and in such activities as glassmaking. Coal, the first fossil fuel to be widely used, was an even more efficient source of heat than was wood, and iron would turn out to be a far more durable building material. But coal and iron had to be mined, and mines tended to fill up with water. A primitive steam engine, known as the “miner’s friend,” was patented in 1698 by Thomas Savery (1650?–1715), an English engineer from Devonshire, and could be used to remove water from mine shafts. Savery’s engine was improved and made much safer by Thomas Newcomen (1663–1729), a Devonshire blacksmith. Newcomen’s engine was highly inefficient, however, because much of the energy released by burning coal was wasted reheating the engine’s one cylinder, which was cooled as a part of its operating cycle. It remained for the Scottish inventor James Watt (1736–1819) to introduce a second cylinder for

condensing the steam, allowing the power-generating cylinder to remain warm. Watt produced a working model by 1775, and Watt’s company had installed forty engines in the mines of Cornwall by 1880. Watt continued to improve the steam engine, which found increasing use in factories as well as mines. By 1800 more than five hundred steam engines were in commercial use.

The steam engine represented the first use of heat energy to perform mechanical work. Prior to its invention, the only power sources available to industry were those of human and animal muscle and the energy of flowing water and the wind, the availability of which were somewhat restricted by geography. A steam engine, however could be installed anywhere water and fuel were available. The steam engine is a good example of the interaction of science and technology during the Industrial Revolution. The earliest versions, those of Savery and Newcomen, were the products of a process of trial and error, with little base in scientific theory. Indeed, a proper scientific theory of heat was not available until the mid-nineteenth century. Watt, although not a university graduate, worked at the University of Glasgow and was acquainted with some of the leading scientific minds of his time, in particular Dr. Joseph Black (1728–1799), who introduced the concepts of latent heat and specific heat, which were essential to understanding the operation of the engine. Watt’s designs also required that workers be able to produce parts to exacting tolerances, requiring that they master more sophisticated tools and measuring devices.

Building better steam engines would become one of the primary motivations for the development of the science of thermodynamics, which connects heat and mechanical energy. In 1824 the French physicist Sadi Carnot (1796–1832) published “Essay on the Motive Power of Heat,” in which he showed that there is a fundamental limit to the efficiency of any heat engine, a limit that is set by the temperature of the environment. Thus any process in which heat is produced for conversion into mechanical energy results in the release of heat to the environment.

The Textile Industry

The climate and terrain of Britain and Scotland were highly suited to sheepherding, and many farm households were involved in the spinning of wool and manufacture of woolen garments. They had also begun the manufacture of cotton cloth. Cotton was available to the English from plantations in the southern United States, the Caribbean, and the Middle East. Whereas the cost of growing a pound of cotton was much less than that of a pound of wool, converting cotton into cloth was a more labor-intensive process. The importation of cotton fabric from India led to interest in the possibility of manufacturing cotton garments in England.

The basic operations in the production of cloth are spinning, in which short fibers are wound into a continuous thread or yarn, and weaving to form cloth. The first major invention in textiles during the Industrial Revolution was that of the flying shuttle loom, patented by the English inventor John Kay (1704–1768) in 1733. The improved loom greatly improved the speed with which thread could be woven into cloth, creating a demand for more production of yarn, a demand met by the spinning jenny, introduced by James Hargreaves (1720–1778) in 1764, making it possible to create multiple strands of yarn at the

same time. Hargreaves's spinning jenny produced a relatively weak yarn, however. Sir Richard Arkwright (1732–1792) invented a machine in which, by careful control of tension in the fibers, a much stronger thread was produced. Both Hargreaves and Arkwright were forced to relocate by their neighbors, who felt that they would be driven out of the market as producers of thread and cloth. By 1778 twenty thousand spinning machines were in operation. Steam engines were installed as "prime movers" in the textile factories, providing mechanical energy to the spinning machines and, later, power looms. In 1793 the American inventor Eli Whitney (1765–1825) began production of the cotton gin, a device that greatly speeded the removal of cotton seeds from cotton fiber, assuring an increased supply of raw cotton, which English textile manufacturers eagerly imported.

The Iron Industry and Transportation

The extraction of iron from its ores and its use in construction greatly expanded during the Industrial Revolution. Iron production is very costly in terms of energy. Wood does not burn at a high enough temperature to be used directly to heat the ore, so charcoal had been used instead. The copper industry had begun using coke, a purified form of coal, as a more

Gustave Caillebotte, *Factories at Argenteuil* (1888). Oil on canvas. The railroad line connecting Paris to Argenteuil transformed this small town on the Seine, once noted for its asparagus and wine grapes, into a *petite ville* combining fine residences and river walks with tanneries and chemical plants—and enough aesthetic appeal to attract the Impressionists.

reliable heat source. Abraham Darby (1678?–1717), an English engineer working in that industry, realized that coke could be used effectively in iron extraction as well. In 1708 he opened the Bristol Iron Works Company and within a few years was manufacturing the huge cylinders needed for the Newcomen steam engines being installed in numerous coal mines.

Numerous advances in land and water transportation facilitated the Industrial Revolution. Canal building by private landowners had been a tradition in England. In 1760, however, Parliament approved using public funds for the construction of the Bridgewater Canal, which was about 16 kilometers long, to carry coal from the coal mines at Worsely to the manufacturing city of Manchester. This reduced the cost of coal to the textile manufacturers by about 50 percent. The success of the Bridgewater Canal was followed by a period of extensive canal building, with nearly fifty additional canals being built by the end of the century and industrialists establishing factories on sites that would reduce their transportation costs.

England also enjoyed a strong navy and a merchant marine fleet. Navigation on the open sea was rendered much safer by John Harrison (1693–1776), a carpenter and clockmaker who invented a chronometer

that remained accurate on ship and thus could be used, together with astronomical observations, to determine longitude. Sailing remained dependent on wind, however, and thus somewhat unpredictable until the invention of a practical steamboat by the American inventor Robert Fulton in 1787. By using Watt's steam engine to power a paddlewheel and later a propeller, Fulton made water travel faster and more dependable.

The steam locomotive appeared in 1802 when English inventor and engineer Richard Trevithick (1771–1833) commissioned Darby's Bristol ironworks to produce the first locomotive engine. The railways would become the biggest consumer of industrial iron, required both for the steam-powered trains and the rails they rode on. Although only 320 kilometers of rail were operating in 1820 (all of it in Britain), thousands more would be installed by midcentury.

Social Consequences

The Industrial Revolution occurred in England at roughly the same time as the American and French Revolutions. Although the three revolutions were dissimilar in many regards, they all had the effect of greatly diminishing the power of a landed and hereditary aristocracy: in France by execution, in America by political action, and in England by the accumulation of wealth by a new class of entrepreneur. As a result, social mobility greatly increased, and a new class of technically skilled working men, machinists, draftsmen, and engineers emerged. At the same time the status of unskilled or semiskilled workers diminished. Factory workers were required to report for work seven days a week, ten or more hours a day. Many procedures had to be completed while the machines were still running because it was too costly to interrupt production. Many workers, including many children, were maimed as a result. Eventually child welfare laws and unionization would reduce the human toll of industrialization while more enlightened manufacturers came to appreciate that well-paid and healthy workers would be more productive and

China, the world's largest expanding market (and the world's most populous country), is a hubbub of construction and industrialization in the twenty-first century.

ultimately an important part of the market for manufactured goods.

The Developing World

The prosperity of the United States, England, and countries of northern Europe as industrialized nations is widely envied by nations in the developing world, and many poorer nations have set upon an agenda of industrialization. Becoming an industrial power, however, is difficult without a stable currency and government and a literate population. Cultural considerations also come into play; not all cultures share the European notion of progress. Because industrialization requires energy sources, industrializing nations and the international community must weigh the benefits and risks of the increased use of fossil fuels, if available, against those of nuclear power plants that might be built. There are also limits to the role that governments can play in stimulating industrialization. The leadership of the former Soviet Union was able to industrialize the production of military hardware and farm machinery but had little to offer

in the way of consumer goods. Industrialization is making headway in the Pacific Rim as multinational corporations find it easier to manufacture electronic goods in countries with cheaper labor and less stringent environmental laws. How best to facilitate the industrialization process without further deterioration of the global environment remains an issue of international debate.

Information Storage and Recovery

Humans survived through millennia by passing on knowledge through stories, ideographs, and pictures. Sumerians (circa 3000 BCE) and Chinese (circa 1500 BCE) were the first to develop rudimentary writing methods. Information was soon stored in encyclopedic form, in libraries, and, after the fifteenth century, further disseminated in mass-produced books. Fast-forward to the twenty-first century; computers and the Internet have redefined what it means to “look something up.”

Knowledge is lost if it cannot be stored and retrieved. Throughout most of the five hundred thousand years of human history, the storage methods employed were primitive at best. The only means ancient tribal people had for transcribing information was through the use of ideographs and pictures drawn on cliff faces and cave walls, or by cutting meaningful notches into strips of wood. Most knowledge was passed from one generation to the next through the repetition of stories and the use of rhyming memory clues. Such stories, much like the tales told among primitive people today, transmitted social codes, related tribal history, and taught the young about what the old generation knew of the dangerous and benign animals and plants in the natural world. The number of such stories told over the entire span of human development must be enormous. The U.S. anthropologist Melville Herskovits estimates that today’s African tribes have between 200,000 and 250,000 stories. The number of recorded tales among the North American Indians also runs into the thousands, and then there are those of today’s tribes in Polynesia, Australia, and other parts of the world. Most of these

stories are rhythmic and repetitive, filled with emotion and visual details that act as an aid to the exact transmission of the content.

Ancient Record Keeping

We are so accustomed today to seeking information in libraries, dictionaries, encyclopedias, and on the Internet that it is somewhat difficult to visualize societies in which children grew up learning only the things that adults passed on to them by word of mouth. When people finally did develop rudimentary methods of writing, they first used this skill only for recording rather mundane matters such as imprinting to denote ownership, listing barter transactions, and producing magical incantations. It wasn’t until the Egyptians developed papyrus about 4000 BCE that information could be written and preserved on scrolls and later in books to be easily moved from place to place and stored in libraries. Around 3000 BCE the Sumerians, who lived in Mesopotamia, first reached the level of primitive writing using a rudimentary alphabet. The Chinese independently developed their form of writing about 1500 BCE employing separate symbols for each word. Over the centuries the Chinese kept adding symbols until their language today uses about 50,000 separate characters, all based on those first introduced during the Shang dynasty (1766–1045 BCE).

Handwritten papyrus scrolls and later printed books were often collected together in private and public libraries where authorized persons could view them. The famed library at Alexandria is estimated to have had several hundred thousand papyrus scrolls in its storage bins, most containing a

Tourists view the ancient petroglyphs on Newspaper Rock State Historic Monument at Indian Creek Canyon, Utah. The Anasazi peoples created the earliest of these images about 2,000 years ago. National Archives.

wealth of information acquired by the Egyptians and Greeks. All of these were lost when the library was destroyed during a time of military siege. It is said that the victors burned the scrolls to heat the public bath water. This is not the only recorded disaster to thwart the accumulation of knowledge. In the mid-1500s, Bishop Diego de Landa ordered the Spanish conquistadors to burn all the Mayan bark-cloth books they could find, because these “contained nothing but superstitions and falsehoods of the Devil.” The great collection of Mayan astronomical knowledge was thus destroyed, as were all the Mayan officials and intellectuals who knew how to read the texts. Archaeologists are still trying to decipher the few manuscripts that survived.

Encyclopedias: Circles of Knowledge

To the ancient Greeks, knowledge was static and not dynamic. They held that, once understood, the world could be controlled; that it never changed even as new things were discovered about it. The Greeks set about gathering all the known facts and recording them on scrolls that later became known as encyclopedias (*enkyklios*, meaning circular or complete, and *paideia*, meaning education). Pliny the Elder (23–79 CE) used the two words in this way in his preface to *Natural History*, where he says that he treats all the subjects of the circle of learning. Pliny’s work consisted of 37 parchment scrolls and 2,493 articles.

History, however, awards the title “compiler of the first encyclopedia” to Speusippos, the nephew of Plato who took over the leadership of the Athens Academy after Plato died in 347 BCE. Only fragments of the work by Speusippos survive, but we do know that he intended his encyclopedia to be a teaching aid for use in lectures at the Academy.

The first Roman to produce an encyclopedia was Marcus Porcius Cato (234–149 BCE), a general and quite prominent citizen of Rome. His work, *Præcepta ad Fillum*, covered the subjects of agriculture, law, medicine, oratory, and war. The entire text was eventually lost but other Roman encyclopedias of note for which we have remnants are those produced by Marcus Terentius Varro (116–27 BCE) and Aulus Cornelius Celsus, the latter a twenty-six-volume work written during the reign of Tiberius (14–37 CE).

Like the Greeks the ancient Chinese established academies of scholars to gather all their knowledge so that it could be passed on to later generations. Their first encyclopedia was the *Huang Yan* (Emperor’s Mirror) prepared under the order of an emperor about 220 CE. No part of this work survives, but later Chinese encyclopedias describe it as a carefully structured work written in fine literary style. The Chinese also produced the world’s most extensive encyclopedia, encompassing 11,095 volumes and over 500,000 pages. This is the *Yongle dadian* (Great Compendium of Yongle). Some 2,000 scholars, commissioned in 1403 by Zhu Di (known as the Yongle Emperor),

Two pages of the *Yongle dadian*. Of its 11,075 original volumes, 370 survive, now scattered in libraries all over the world.

finished their work in 1408. A total of 370 volumes of this massive encyclopedia survive, now scattered in libraries all over the world.

Ibn Qutaiba (b. 828 CE), a teacher and philologist, produced the first Arabic encyclopedia, which was titled *Kitab Uyun al-Akhbar* (The Best Traditions). The work was divided into ten books covering asceticism, character, food, friendship, learning and eloquence, nobility, power, prayers, war, and women. Other Arabic encyclopedias followed, including a noted medical encyclopedia by Averroes (1226–1198) called *Al Shifa* (“the Healing”). Throughout much of the medieval period in Europe, Islam flowered in scholarship and preserved many of the Greek and Roman texts that had been forgotten or destroyed in the Christian world. Not until the later Middle Ages did Christian scholars, through Arabian contacts, begin to rediscover and collect this wisdom.

Medieval Europe did, however, produce a number of encyclopedias filled with the somewhat limited interests of the Christian communities. One of these was the twenty-volume work *Originum seu Etymologiarum Libri XX* (Study of the Origin of Words, Book 20) by St. Isadore of Seville (c. 560–636). It is unique for its time because Isadore’s starting point was the liberal arts rather than theology. Most of the medieval encyclopedias were compiled, without acknowledgement, from bits and pieces of other people’s work. Plagiarism was apparently a natural outgrowth of the medieval copying process.

One such work deserves mention—because of its fine craftsmanship and because it was produced by a woman, Abbess Harrad of the Hohenburg convent near Strasbourg, in Alsace. Her encyclopedia, called the *Hortus Deliciarum* (Garden of Delights), was completed shortly before 1195 and is one of the finest examples of illuminated manuscripts ever produced.

With the return of wide-ranging scholarship during the Renaissance, along with the development of the printing press to produce multiple copies of books, encyclopedias by many authors became commonplace. Some of the most notable among these were one by the English clergyman John Harris, who was the first to arrange entries alphabetically (1704); one by the German Johann Zedler that was the first to include biographies of living persons (1732); and the *Encyclopédie* by the French scholars Denis Diderot and Jean D’Alembert (first part published in 1751), which was not only superb in terms of scholarship but was banned by the French government prior to the French Revolution because of its “subversive content.” A few words should also be said about the *Encyclopaedia Britannica* that first came out in the form of a series of pamphlets (a hundred installments) between 1768 and 1771. These pamphlets could be stitched together later and bound into three leather-covered books. The *Britannica*, which has since been published in many editions, established a form that has been followed by many encyclopedias—extensive

“In the Time of the Ptolemies: The Alexandrian Library,” illustration by J. André Castaigne from *Harper’s Magazine* (May 1908). New York Public Library.

articles, some more than a hundred pages in length, on broad general topics. Modern encyclopedias are found in almost every language and are published in every advanced nation.

Accessing Information

The problem of finding an exact item of desired information among the mass of stored data is certainly not new, although today’s magnitude of data may be. More than 5,000 years ago the Assyrians tried to deal with this problem by inscribing notations on their clay information cylinders in characters so small they are almost unreadable. The Sumerians devised a kind of index to mark their clay tablets. But the concept of organizing information into useable categories and sub-categories only became popular during the sixteenth century. One of the prime movers in this was the English philosopher and statesman Francis Bacon, who attempted to arrange his comprehensive view of knowledge into logical sections and sub-sections that would be useful to any literate

person. Bacon’s method, published in a section of his *De Augmentis Scientiarum* (1623), was consulted and somewhat utilized by a number of persons who in later years compiled encyclopedias, and it was highly praised by Diderot in his *Encyclopédie*. The poet and essayist Samuel Taylor Coleridge (1772–1834) also tried to encompass all human knowledge in a carefully structured design intended for an encyclopedia that was never completed. Coleridge deplored the alphabetical arrangement in some of the more popular encyclopedias of his day because such an arrangement was only “determined by the accident of initial letters.”

Disorganized knowledge is of almost as little value as no knowledge at all, and therefore every library has needed some system by which to arrange the variety of books. President Thomas Jefferson, for his own library, adopted the system advocated by Francis Bacon. A method still in use in many libraries around the world is that developed by the American librarian Melvil Dewey (1851–1931). This Dewey decimal system divides books into ten main categories, each represented by a three-digit number ranging from 000 to 999, with each of the ten groups further divided into more specialized fields by subsequent numbers following a period.

All the storage and recovery systems of the past have now been dwarfed by digital computers and hypertext. Developed in 1944, the first digital computer, called Mark I, was a massive machine controlled by a series of mechanical and electrical devices. It bore little resemblance to the desktop and laptop machines of today, and its primary use was for rapid mathematical computations. Within a few years the storage capacity of computers grew at an astounding rate so that today virtually anything that can be digitized (represented by a discrete set of its points) can be stored on a computer—words, images, sounds, and more. The massive memory modules on large mainframe computers now have the ability to store all the recorded knowledge of all the libraries in the world in a single location. By March 2007, according to *The New York Times*, the popular computer web browser, Google, had digitized

one million out-of-print books, and by 2009 it had digitized about six million. Anyone with a computer can access any or all of these books from their own living rooms.

Such an overload of information would be impossible to manage were it not for use of hypertexting and the rapid indexing ability of computers. Hypertexting is the method by which certain words in text displayed on a computer are marked (hyperlinks) so that a reader can, with a keypress sequence or mouse click, immediately access similar occurrences of that text within other parts of the document and even in other documents. The computer's indexing ability allows a user to immediately locate specific words or phrases in any displayed text by merely typing what is wanted in a "find box."

Thus the ability of human beings to store and recover the knowledge they acquired has grown

from simple memorization methods through written documents and books to complex computer storage systems that no one could have imagined fifty years ago.

Initiation and Rites of Passage

Societies use rites of passage to acknowledge the transitions individuals undergo throughout life—from childhood to puberty, for example, or the induction into a particular group. Such rites vary widely from culture to culture over time. In the context of world history the patterning of rites of passage is well illustrated by the adolescent initiation rite, perhaps the best-studied instance of a rite associated with a life transition.

The term “rite of passage” refers to any ritual that marks a transition in the life of an individual from one state or status to another. All human beings experience a series of such transitions in the course of a lifetime. Transitions can reflect biological or maturational progressions. So, for instance, birth marks the maturational transition from existence within the womb to life in the outside world, puberty marks the maturational transition from sexual immaturity to sexual maturity, and death marks the maturational transition out of the realm of the living. Individuals may also experience transitions in educational, occupational, legal, or social status, in-group membership, and role assignment. Graduation from school, certification into a profession, marriage, the shift to a new social class, acceptance into a fraternity or sorority, and parenthood are all examples of such transitions. Human societies tend to mark such life transitions with rites of passage. Baptisms, naming ceremonies, hazings, bar mitzvahs, coming-out balls, graduation ceremonies, induction rituals, weddings, and funerals are examples of rites of passage. A ritual that has elements of a rite of passage may also simultaneously serve other purposes. So,

for example, a marriage may mark the transition of the prospective spouses from the status of single to married and also promote fertility of the couple.

Structure of a Rite of Passage

Rites of passage are found in every known human society, past and present. Additionally, these rituals tend to share certain broad structural features in common. Thus, any rite of passage typically begins with a formal separation of the transitioning individual from the old state or status. The person then remains for some period of time in a marginal or transitional state divorced from both past and future statuses. Finally, in the incorporation phase of the rite, the transitioning individual enters into the new state or status. The substantive details of a specific kind of rite often symbolically mirror the nature of the specific transition that it is marking. For example, a birth ceremony, which celebrates the entrance of a person into the world, is likely to emphasize the incorporation phase of the rite, while in a funeral ceremony, which marks the departure of the individual from the world, the separation features of the ritual might be elaborated. Further, the content of a rite may be a symbolic reference to some aspect of the transition that it is marking. So, an opening door may mirror the idea that the individual is entering a new status. Similarly, the incorporation of a person into some new status may be reflected in the acts of eating and drinking, themselves a kind of incorporation of sustenance into the body. The similarity in the overall structure of rites of passage across cultures dramatizes the striking historical uniformity in the way in which human societies negotiate life transitions.

Jewish marriage ceremony, Turkey (1862).

Public Library.

Universal Function of Rites of Passage

The fact that human beings across historical time and place mark life transitions in a similar way points to the likelihood that rites of passage may serve a similar purpose for the people who participate in them. The key to the historical and geographical uniformity characteristic of rites of passage may be found in the pan-universal nature of life transitions. In particular, transitions from one state or status to another have the potential to disrupt the smooth functioning of the community at large and the psychological functioning of the transitioning individual. For example, birth, marriage, and death can disturb the normal relationships among individuals in a family, community, and society. Rites of passage, then, are proposed to serve as the strategy devised by human societies to mediate whatever social upheaval and personal turmoil are associated with life transitions.

Variations in Presence of Rites of Passage

Differences are also apparent with respect to how life transitions are handled across cultures. Societies vary regarding which transitions are marked with rites of passage. Differences also occur from one time and place to the next with regard to the details of the rites and the degree to which they are elaborated. Rites may be more or less important, intense, or prolonged in one society as opposed to another. Such differences are in part accounted for by variations in certain identifiable features of a society. Salient among such features are population size and the degree to which cultural institutions are subject to change. Thus, rites of passage tend to be most elaborated in small-scale, more or less stable cultures. By contrast, in large societies characterized by technological innovation, rites are less prominent. Similarly, rites of passage take on more importance in cultures with a high degree of status differentiation, while rites are less important where status differences are underplayed. Rites are also more common in places where fine distinctions are made among people, for example, of different chronological ages, from various occupational groups, and so on.

Each of the trends described above is consistent with the idea that rites serve to manage disruptions that life transitions can generate. Thus, such disruptions are most likely, and likely to be most intense, in small societies where individuals interact with a small number of cohorts. This is because the position and behavior of any single person is maximally likely to affect others in such groups. Further, where stability in institutions and behavior is valued, change has maximum potential to threaten the group. In large groups and in groups open to change, by contrast, the status or behavior of any specific individual or class of individuals has less potential to threaten or actually affect the circumstances of the remaining members of the group. Further, in a society typified by change, as is the case in technologically innovative cultures, rites of passage become difficult to execute. This is because the transition phase of a rite

Initiation dances as they are performed on Sioeban, Sipoera Island, part of the Mentawai Islands, Indonesia. The spirit house at Oema is shown at bottom right. Photos by Paul Fejos. New York Public Library.

of passage includes quite specific content regarding the roles, rights, and responsibilities accorded to the individual entering into a new state or status. In a changing society, as the future is likely to be different from the past, the idea of incorporation into a new status with known roles and rules is compromised. Finally, where differences among groups are meticulously defined, membership in such groups may be more difficult to achieve, promoting the need for a rite of passage. Such a ritual would include tutoring of the individual in the detailed rights and responsibilities of the new state. It might also certify the person as a member in good standing of the new group, thus promoting acceptance of the initiate by already established members. In summary, the patterning of rites of passage from one place to the next, including differences in how rites are played out, is attributable to the nature of a society at a specific moment in history. As relevant features of a society change in historical time, so will the specific manner in which the society reacts to the inevitable life transitions of its members. As population grows larger, as it becomes characterized by innovation, and as it increasingly devalues status distinctions, rites are predicted to become less important to the culture.

Historical Trends

The societal features associated with the presence (or the absence) of rites of passage tend to follow an historical timeline *within* the culture in which they are found. So, any single society may progress from small to large, preindustrial to industrial, and stable to innovative. Societies have also been shown to progress from egalitarian to status-based and back to egalitarian. Thus, the lives of people living in simple societies, for instance those based upon a forging economy and people living in contemporary industrial societies, tend to be less constrained by issues of status than are the lives of people living in middle-level societies depending upon agriculture for their subsistence. This means that the presence and patterning of rites of passage will follow a predictable trajectory consistent with the historical timetable of a specific culture. But different societies will be at different points in the overall progression from simple to complex, small to large, preindustrial to industrial, and egalitarian to nonegalitarian at any given moment in history. This means that, at any point in historical time, different societies will employ and elaborate rites of passage differently.

Adolescent Initiation Rites

The connection between the patterning of rites of passage and historic context is well illustrated by the adolescent initiation rite, perhaps the best-studied instance of a rite associated with a life transition. The adolescent initiation rite is a ritual that mediates the shift of an individual from the socially recognized status of child to that of adult. Adolescent initiation rites, when they are adopted by a society, often take place at or around puberty. Although the adolescent rite is thus often linked to a physiological change, these rituals are understood to achieve their importance because they confer a new *social* status on the initiate.

Patterns

According to *Adolescence: An Anthropological Inquiry* (Schlegel and Barry 1991), adolescent initiation rites of some sort are found in roughly half of the societies around the world for which information is available. In societies with an adolescent rite, all young people must participate in the ceremony. Sometimes, a society will hold an adolescent initiation rite for only one sex, in which case only members of that sex take part as initiates. Members of the opposite sex may still act as participants in the ceremony. If both sexes undergo an initiation rite, the male and female rituals are held separately. Adolescent initiation rites are somewhat more commonly held for girls than for boys, perhaps because menarche is such a clear and unambiguous mark of sexual maturity, making it easier to establish an appropriate time for the female's transition to adult status. On the other hand, adolescent male initiation rites are usually more intense and dramatic than are those held for females, typically including as they do physical ordeals, events meant to induce fear in the initiates, and hazing.

Male adolescent initiation rites are most commonly found in Africa and the insular Pacific, while over half of the societies with female adolescent initiation ceremonies are found in Africa. African initiation

rites often include circumcision for boys and, less frequently, cliteridectomy and tattooing for girls. The vision quest, a kind of adolescent initiation rite, was traditionally found among some North American Indian tribes and might be undertaken by either sex. During such a quest, a young person spent some days alone in the forest fasting and waiting for a vision in which the supernatural would reveal to the boy or girl some information pertaining to the young person's future role in life.

Structure

The adolescent initiation rite follows the overall pattern of rites of passage more generally, whether it consists of a public ceremony, as is often the case in Africa, or an individual quest, as is found in indigenous North American groups. The boy or girl is initially separated from his or her former life. Symbolism may play a role in the separation so that, for example, the adolescent may be physically removed from the parent's household. The transition phase is at least in part a preparation for the adult role. The adolescent may be taught important traditions of the society as well as the skills that will be needed in the new status of adult man or woman once the transition is complete. Or the young person may gain important information about the direction that his or her adult life will take, as is particularly the case in the vision quest. The rights and obligations of adulthood will also be communicated in detail. Importantly, it is the older generation that is in charge during an initiation rite. The initiate's demeanor is of total subservience. This is the case whether the initiation rite is in the form of a public ceremony, as is often the case among African societies, or is an individual affair, as in the North American vision quest. During the final, incorporation phase of the rite, the initiate is reincorporated into the society as a whole. Usually, the initiate is also now recognized as a full-fledged adult by all other members of the group, although this is less universally the case at the end of a vision quest.

Variations in the Presence of Adolescent Initiation Rites

As is the case with rites of passage in general, adolescent initiation rites are more common in small-scale, preindustrial cultures. Societies with adolescent rites are typically homogeneous, with sparse or nomadic settlement patterns. Female initiation rites are found more often where people hunt, gather, or fish for a living, and where descent is traced either through females or through both sexes as opposed to males only, as established by V. R. Burbank (1997) in “Adolescent Socialization and Initiation Rites.” If husbandry is practiced, it is of pigs, sheep, and goats, and not larger animals. In general, female initiation rites are more frequent in what anthropologists term simple societies, that is, societies without class stratification, specialization of occupation, complex political hierarchy, private property, or individual inheritance rules. Male adolescent rites are found in

societies where gardening is the main form of subsistence and where descent is traced through males.

Functions

A number of functional explanations of adolescent initiation rites have been proposed. All of these explanations link the presence of adolescent rites to some specific feature of society in its historical timeline. Thus, the adolescent initiation rite is viewed as a technique of socialization that allows the young persons’ knowledge and mental outlook to be made compatible with some feature of his or her culture. Potential collisions between the youth and the society are thus minimized as the adolescent makes the transition to adulthood.

In keeping with this interpretation of the function of adolescent initiation ceremonies, the general association between rites of passage and status distinctions has been extended to an explanation of certain

A seventeen-year-old boy in ancient Rome receives a toga, traditionally worn only by adult male Roman citizens, as part of his rite of passage. New York Public Library.

These mysteries, like the Masonic rites, are ones parents and elders are sworn not to reveal to the uninitiated, which include all children. And so we [children] sought for signs. • **Anthony Hecht (1923–2004)**

patterns of male adolescent initiation rites in particular. The idea here is that, where societies emphasize distinctions between the sexes, male initiation rites, especially those including circumcision, will serve to underscore and maintain the distinction. Male adolescent initiation rites have also been interpreted as a strategy for creating solidarity among men in societies where close ties among males is important. The association between male adolescent initiation rites, horticulture, and moderate cultural complexity has been explained in this way, the assumption being that these societal features create the context for exclusive male organizations.

Rituals for adolescent females have similarly been linked to certain features of society, and especially to the place of women in a culture. Thus, the initiation rite for females has been explained as a way of dramatizing the transition from girlhood to womanhood when married couples traditionally live with or near the wife's family (matrilocal residence) and when women make an important contribution to the subsistence economy.

Educational Function

Whatever particular social structural features may account for the presence of adolescent initiation rites in different societies, all such rituals seem to also have one purpose in common, and that is the function of educating the young person. Initiates are given detailed instructions about their roles, responsibilities, and privileges as adults in the culture in which they live. They are also instructed in the culture's mythology and system of ethics. The manner in which the individual's adulthood life will be played out, as a result, is largely determined by the older generation.

The initiation rite among the Ndumbra of New Guinea illustrates the educational aspect of the ritual. In his study about adolescent initiation rites, Burbank (1997) describes how, in this culture, boys undergo a three-day initiation ceremony in groups of perhaps five or six initiates. Mothers dress and decorate their young sons, and a group of men then comes to collect each boy and take him into the forest. The mothers

pretend to protest. We thus see the separation of the boy from his old role as child dramatized in the ritual. The initiation proper consists of number of physical ordeals and humiliations and also intense instruction regarding the various taboos that must be observed by adult men in their culture as well as the consequences of nonobservance of the taboos. Upon completion of the rite, boys are viewed as true warriors and begin to live in a special house reserved for males. According to I. Hilger's (1951) study of the Chippewa, the educational aspect of the initiation rite is similarly illustrated by the Chippewa initiation rite for adolescent girls. In this indigenous North American Indian society, an adolescent female, at her first menstruation, is secluded for a number of days in a wigwam built by the girl herself. The isolation of the girl is due to the belief that, as a menstruating woman, she is dangerous to the community, who must be protected from her. But also, during her seclusion the girl is tutored by her mother on her future role as an adult woman.

Disappearance of Adolescent Initiation Rites

Wherever the adolescent initiation rite is found and whatever specific function it performs, it is the older generation that is in control of the ritual. The payoff for the young person is that, at the completion of the ceremony, the initiate is accorded full status as an adult. This is possible because adolescent initiation rituals tend to be found in small, stable, homogeneous societies. It is in societies of this sort that the adults have knowledge of moral dictates, community traditions, rituals, practical knowledge, and so on. Where a society is large, complex, heterogeneous, and rapidly changing, the knowledge residing in the older generation is less likely to be relevant to the younger person. Indeed, in such societies, adolescents may be left on their own to construct their own adulthoods, including what they will be, what they will believe, how they will behave, where and with whom they will live, what moral standards they will follow, and so on. This is the case, for instance, in industrialized societies, where initiation rites, if they exist at all, no longer

serve the function of educating the young person in his or her future role as an adult or of conferring adult status. The result of this is that young people may be unsure as to what the adult role entails when they have in fact achieved the status of adult. On the other hand, adolescents living in large, heterogeneous, changing societies also have a kind of freedom to pursue their own interests and develop their own talents that a young person living in a small, homogeneous, stable society does not enjoy. Sometimes, when the culture at large no longer provides a rite of passage to smooth over some life transition, individuals themselves may evolve their own rites of passage. The psychologist George Goethals (1967) has explained the male adolescent gang as an example of an attempt on the part of youth to map out their own roles and rules when the society no longer provides them guidelines.

Implications

The presence, importance, and elaboration of both rites of passage in general and adolescent initiation rites in particular are contingent upon certain features of a society, which have been described in this article. Thus, rites of passage in general, and certain kinds of these rites, are more likely to be found in some kinds of societies and less likely to be found in others. When a society changes, either by virtue of internal processes or as a result of external influence, rites of passage may become more or less prevalent. It is the place of a particular society *in its own historical trajectory* that seems to most influence how that society will negotiate the life transitions of their members.

International Court of Justice

The International Court of Justice (ICJ), located in The Hague, is one of six main organs of the United Nations. The ICJ's role is to settle legal disputes submitted by member (or other approved) states and to act as a legal adviser. Difficulties encumber the ICJ's function as a true international tribunal, most importantly because states party to a dispute must submit to the authority of the court.

Popularly known as the World Court, the International Court of Justice (ICJ) is one of the six main organs of the United Nations. As the U.N.'s principal judicial organ, it is the successor to the Permanent Court of International Justice, which was formally dissolved in 1946. The ICJ operates on the legal basis of Chapter VI of the U.N. Charter, which concerns peaceful settlement of disputes, and the Statute of the International Court of Justice, which is an integral part of the U.N. Charter. All 191 member states of the United Nations are ipso facto parties to the Statute, but nonmembers may become parties as well if approved by the General Assembly and the Security Council.

Located in The Hague, the Netherlands, the Court is composed of fifteen judges elected for nine years (five being elected every three years), with the possibility of being reelected by the General Assembly and the Security Council. Candidates for ICJ judgeships are nominated by national groups in states, and are elected as individuals regardless of their nationality, although no two judges may be nationals from the same state. By tradition, the permanent members of the Security Council (China, France, Russia, the United Kingdom, and the United States) have judges

elected to the court, although China had no judge during the period from 1960 to 1984, due to the controversy over Taiwan and China's representation in the U.N.

Since the ICJ functions as an institution that interprets and applies law, it possesses certain advantages over other methods of dispute settlement. For one, the Court operates on a continuous basis, so it is always prepared to deal with disputes. For another, it contributes to the development of a shared body of legal rules, both substantive and procedural, through which differences between states can be resolved. In this regard, both disputant states must voluntarily consent to appear before the Court, judgments are binding, and there is no appeal. Since 1946 the Court has entered 144 cases into its General List, many of which concerned disputes over contentious issues, among them land frontiers and maritime boundaries, territorial sovereignty, the nonuse of force, noninterference in the internal affairs of states, diplomatic relations, hostage-taking, the right of asylum, nationality, guardianship, rights of passage, and economic rights. Importantly, nearly all these decisions were accepted and implemented by the participating states. In fact, more states are submitting more cases to the ICJ than ever before, with fourteen on the court's docket in 2009. The ICJ may also render advisory opinions at the request of any of the other five organs of the United Nations, or the sixteen specialized agencies under the Economic and Social Council in the U.N. system. That competence is used to advise the requesting organ on the legal status of questions (as in the case put forward in 1985 by the U.N. General Assembly on the lawfulness of nuclear weapons) or to declare a legal opinion on the issue in

Photograph of the Peace Palace in The Hague, the Netherlands, taken for the sixtieth anniversary of the International Court of Justice in 2006.

question. Since 1946 the Court has rendered twenty-four advisory opinions on a wide variety of issues, such as admission to United Nations membership, reparation for injuries suffered in the service of the United Nations, the territorial status of South-West Africa (Namibia) and Western Sahara, the status of judgments rendered by international administrative tribunals, expenses of certain United Nations operations, the applicability of the United Nations Headquarters Agreement, the legality of the threat or use of nuclear weapons, and the lawful status of the wall being constructed by Israel to separate that state from Palestinian territory.

Certain difficulties still encumber the ability of the ICJ to function as a true international tribunal. Most important is that states party to a dispute must be willing to submit to the authority of the Court. In that regard, there still exists a fundamental problem of mistrust. Not all U.N. member states are mandated to appear before the Court. Some, including the United States, have reserved the right to make final judgment on whether the case involves their domestic jurisdiction, which means in effect that they can refuse to accept jurisdiction. The ICJ only retains that jurisdiction which governments are willing to grant to it in each case. Such a restrictive tendency diminishes the role that the World Court can play

in resolving major political conflicts between states. The uncertainty of legal rulings, a paucity of legislative institutions with the authority to adjust legal rules to the changing international milieu, and the lack of organized judicial procedures for the enforcement of judgments all contribute to the reluctance to use the ICJ as an instrument for international dispute settlement.

International Criminal Court

The International Criminal Court, which came into existence on 1 July 2002, is a permanent tribunal created to prosecute individual defendants implicated in genocide, crimes against humanity, war crimes, and, in the future, the crime of aggression. The court is located at The Hague in the Netherlands, but it can sit and hear cases almost anywhere in the world.

The International Criminal Court (ICC) is the first global permanent court with jurisdiction to prosecute people for crimes of greatest concern to the international community: genocide; crimes against humanity; war crimes; and, after a definition is agreed upon, aggression. The ICC originated on 17 July 1998, when 120 countries met at the United Nations Diplomatic Conference of Plenipotentiaries on the Establishment of an International Criminal Court. Located at The Hague in the Netherlands, the ICC formally came into existence on 1 July 2002.

The creation of the ICC is the culmination of a decades-long effort to establish an international court with jurisdiction to try people for crimes against humanity. The legal definition of such crimes after World War II was part of the construction of new international legal structures, such as the United Nations, to preserve international peace and security and prevent upheavals capable of unleashing the horrors of modern warfare.

The tribunals designed to prosecute Nazi and Japanese war criminals established the precedent for the ICC. In singling out national agents for international responsibility, the organizers of the tribunals hoped that international criminal law would provide an incentive for high-ranking government officials

to refrain from devising and executing policies promoting atrocities or aggressive war. Additionally, the prosecution of war criminals provided incentive for low-ranking nationals to refuse to obey orders to carry out such policies. The tribunals were expected to contribute to preventing violent conflict between—and atrocities by—nations.

After the Nuremberg and Tokyo tribunals had completed their task, however, initial moves to establish a permanent international jurisdiction to succeed them faltered because of growing hostility between the Soviet Union and the United States. In the atmosphere of suspicion and obstructionism brought on by the Cold War, enforcement was left to national systems. Conflicts continued, and atrocities occurred, often with the acquiescence or direct involvement of one of the superpowers. Not until the 1990s did the international community again prosecute crimes against humanity with the 1993 creation of the International Criminal Tribunal for Yugoslavia (ICTY), and the 1994 creation of the International Criminal Tribunal for Rwanda (ICTR). However, like the Nuremberg and Tokyo tribunals, the ICTY and ICTR were created *ad hoc* (for the particular end or case at hand) with limited jurisdiction.

State Sovereignty

The ICC is designed to transcend politics because trials theoretically will be international, impartial, and nonselective. State sovereignty is protected because the jurisdiction of the ICC is restricted to a relatively small number of cases whose criminality is generally believed to be beyond dispute. Terrorism and drug-smuggling cases, involving matters subject to widely

Justice is a certain rectitude of mind whereby a man does what he ought to do in the circumstances confronting him. • Saint Thomas Aquinas (1225–1274)

different interpretations, remain under national jurisdiction. Yet, a number of nations, especially the United States, doubted that the ICC as created would be truly nonpolitical. Seven nations (the United States, China, Libya, Iraq, Israel, Qatar, and Yemen) voted against the establishment of the ICC, chiefly because of concerns over state sovereignty.

The most contentious question involving the ICC revolves around the level of independence that it possesses in regard to national courts and the United Nations Security Council. The ICC exercises jurisdiction only when national courts of the country in which the crime took place or whose citizens are accused are unable or unwilling to prosecute. The United States seeks an ICC that would be controlled by the Security Council under the reasoning that, as the sole remaining superpower, it was expected to intervene to maintain or restore international peace and security and to halt humanitarian catastrophes all over the world. U.S. fulfillment of that expectation would leave U.S. personnel vulnerable to the potential jurisdiction of the ICC. The United States fears that an independent prosecutor, motivated by anti-Americanism, might single out U.S. military personnel for persecution and that they would be denied the protections guaranteed by the U.S. Constitution.

Structure

Many legal authorities have challenged such fears, citing in particular the structure of the ICC. The court is composed of the presidency, the chambers, the office of the prosecutor, and the registry. The ICC does not provide for trial by jury; instead, it follows the civil law tradition of employing a panel of judges to decide questions of fact and law. Eighteen judges, serving staggered nine-year terms, are permanent members of the court and are elected by secret ballot at a meeting of the Assembly of the States Parties.

The judges elect the presidency and constitute the chambers. On 11 March 2003, the judges elected Judge Philippe Kirsch (Canada) as president, Judge Akua Kuenyehia (Ghana) as first vice president, and Judge Elizabeth Odio Benito (Costa Rica) as second

vice president. On 22 April 2003, the nations participating in ICC chose Luis Moreno-Ocampo of Argentina for a nine-year term as the first chief prosecutor. In his capacity as an Argentine attorney, Moreno-Ocampo has prosecuted Nazi war criminals, Chilean secret police officials, and Argentine leaders of the “Dirty War.” As of 2010 the president of the court is Sang-Hyun Song of South Korea, who was elected on 11 March 2009.

The last element of the ICC, the registry, is responsible for the nonjudicial aspects of the administration and servicing of the court, such as finance, translation, building management, procurement, personnel, as well as services, which are unique to an international court. The latter include administration of legal aid matters, defense counsel, court management, and a detention unit. In addition, in a revolutionary development, a victims and witnesses unit is set up within the registry. This unit enables victims to participate in legal procedures and claim compensation for the first time in the history of international criminal justice. Victims may include rape victims in need of trauma counseling, villagers in need of money to rebuild homes and businesses lost in fighting and, child soldiers who were forced into military service and who may have suffered great ordeals. During its brief existence, the court has received thousands of reports of violations sent by people and nongovernmental organizations from numerous countries around the world, most of which are outside the jurisdiction of the ICC. As of December 2009, three States Parties—Uganda, the Democratic Republic of the Congo (DROC), and the Central African Republic—have referred complaints to the court, while the U.N. Security Council has also referred the situation in Darfur, Sudan, a non-State Party. In respect to Uganda, five arrest warrants have been issued against leading members of the Lord’s Resistance Army. Three cases are being heard as result of investigations in DROC: *The Prosecutor v. Thomas Lubanga Dyilo*; *The Prosecutor v. Bosco Ntaganda*; and *The Prosecutor v. Germain Katanga and Mathieu Ngudjolo Chui*. The Central African Republic case, *The Prosecutor v. Jean-Pierre Bemba Gombo*, a former vice-president of DROC is at

the pre-trial stage. In regard to Darfur, Sudan, three cases are pre-trial: *The Prosecutor v. Ahmad Muhammad Harun* ("Ahmad Harun") and *Ali Muhammad Ali Abd-Al-Rahman* ("Ali Kushayb"); *The Prosecutor v. Omar Hassan Ahmad Al Bashir*; and *The Prosecutor v. Bahr Idriss Abu Garda*. Only Bahr Idriss Abu Garda has appeared voluntarily before the Court, the others, including Sudanese president Omar Al Bashir, remain at large.

As of late 2009, 110 countries had joined the ICC and a further 38 have signed but not yet ratified the Treaty of Rome. Those that have not signed include some the world's great powers home to the majority of our world's population, including China, India, Russia, and the United States.

International Monetary Systems

Goods ranging from cowrie shells (in ancient societies) to cigarettes (in World War II prisoner-of-war camps) have circulated as generally accepted means of payment throughout history, but gold and silver predominated from the eighth century BCE. In the modern world, efforts to peg international currencies against a gold standard were thwarted by balance-of-payment deficits that caused exchange-rate instabilities.

Although the use of goods as a form of payment was accepted throughout history at certain times, ancient societies had already found that coins made from specified amounts of precious metals were more viable and convenient. Authors from Aristotle to Adam Smith noted that gold and silver had the advantages of being divisible, homogenous, and storable (not rusting or decaying through reaction with other elements). In addition, being scarce and costly to produce, gold and silver were highly valuable per unit of weight, so that only small quantities needed to be transported to make payments.

Beginnings

While merchants may have made the first coins, discs containing a specified amount of precious metal, states and cities in Anatolia (modern-day Turkey) and the Aegean coined silver and electrum (a mixture of gold and silver) from the eighth century BCE, with the earliest known gold coins issued in the sixth century by Croesus, king of Lydia in Asia Minor. Solon, in sixth-century Athens, introduced seigniorage, a margin of profit on coinage, by ordering 6,300 drachmae to be minted from each talent of silver, even though

the accepted standard of weights and measures equated 6,000 drachmae (60 minae) to a talent. For centuries, gold, silver, bronze, and copper coins of many rulers and cities circulated, trading externally at rates reflecting their varying metallic content and the changing relative values of the monetary metals. The seigniorage from minting coins with less than full bullion content repeatedly tempted rulers to profit from debasing the coinage, reducing the market value of their coins. In China, copper “cash” was coined, with silver ingots used for large transactions, and Marco Polo was startled to discover paper currency issued by the Chinese state in the thirteenth century CE.

Colonial Era through the Nineteenth Century

The inflow of silver from the newly conquered Spanish colonies of Mexico and Upper Peru (Bolivia) raised price levels and lowered the purchasing power of silver in Europe during the “Price Revolution” of the sixteenth century, but the outflow of silver from Europe to Asia to pay for spices and textiles in the late seventeenth century raised the value of silver. In 1717, Isaac Newton, as master of Britain’s Royal Mint, set the value of the gold guinea at twenty-one silver shillings, a mint price of 3 pounds, 17 shillings, 10.5 pence per ounce of gold (fifteen-sixteenths fine) that was maintained until 1939. Newton overvalued gold and undervalued silver, so, in keeping with Gresham’s Law that bad money drives out good, only gold coins circulated, while silver coins were melted down into bullion. In 1752, David Hume expounded the theory of the specie-flow mechanism underlying the gold standard: if international trade

This nineteenth-century print shows the south facade of the Bank of England in London as rebuilt by Sir John Soane.

and payments were unbalanced, gold bullion would flow from the country with a trade deficit to the one with a trade surplus, reducing the money supply and price level in the deficit country and increasing the money supply and price level in the surplus country. The changing relative price levels would reduce the net exports of the surplus country and raise those of the deficit country until the balance of payments surpluses and deficits were restored to zero. Bank notes were convertible into coin on demand, and coin or bullion was used for international settlements, with a bank raising its discount rate when a gold outflow threatened the adequacy of its reserves. By the nineteenth century, London was established as the world center of finance and commerce, and the Bank of England as the key institution of the gold standard.

The conversion of Bank of England notes was suspended from 1797 to 1821, and the British government paid for its role in the Napoleonic Wars through inflationary finance, with large increases in national debt stock in the hands of the public and of the Bank of England, depreciation of inconvertible Bank of England notes against gold, and a higher price level. Restoration of convertibility at the old parity required a sharp deflation, but was followed by nearly a century of growing world trade and largely stable exchange rates (although the United States was on an inconvertible “greenback” paper standard from the Civil War until the start of 1879). The Latin Monetary Union, a pioneering French-led effort at European monetary unification begun in 1865, linked the French, Italian, Belgian, Swiss, Spanish, and Greek currencies

to a bimetallic standard, but foundered in the face of British and German opposition and the shifting relative price of gold and silver.

Twentieth Century and Beyond

World War I disrupted the gold standard, and was followed by spectacular hyperinflations and exchange depreciations in Central and Eastern Europe, with the German mark stabilized in 1924 at one trillionth of its prewar gold value. John Maynard Keynes presciently criticized Britain’s return to the gold standard at the prewar parity in 1925, warning that the deflation of prices and wages required to remain internationally competitive at a higher exchange rate would exacerbate unemployment. Following the Wall Street crash of 1929, the fixed exchange rates of the gold standard transmitted deflation and depression from country to country, with Britain forced off the gold standard in 1931 and the United States devaluing and ending gold conversion of the dollar in 1933. The Great Depression of the 1930s was a period of fluctuating exchange rates, protectionist tariffs, restrictions on capital flows, and shrinking world trade, a retreat from globalization.

At the end of World War II, the international monetary conference at Bretton Woods, New Hampshire, guided by Lord Keynes and Harry Dexter White, devised a system of fixed exchange rates, adjustable in case of fundamental payment imbalances, with an International Monetary Fund (IMF) to lend foreign exchange, and with the U.S. dollar as the key reserve currency. The dollar was pegged to gold at

Nations have recently been led to borrow billions for war; no nation has ever borrowed largely for education. Probably, no nation is rich enough to pay for both war and civilization. We must make our choice; we cannot have both. • **Abraham Flexner (1856–1959)**

\$35 per ounce, but only other central banks could present dollars to the Federal Reserve for redemption in gold. IMF lending, being conditional on following policy advice designed to end payment deficits, caused friction between borrowing governments and the IMF. Although a few nations floated their currencies (notably Canada from 1950 to 1962), the pound sterling was devalued in 1949 and 1967, and centrally planned economies such as the USSR and China stood apart, the Bretton Woods system provided a stable framework for expanding global trade and investment flows from 1945 to 1973. Persistent U.S. balance of payments deficits undermined the Bretton Woods system, which was followed by a period of exchange rate instability. The Exchange Rate Mechanism, designed to stabilize exchange rates among European currencies, collapsed under speculative attacks such as that against the pound sterling in September 1992. The adoption of the euro as a common currency, initially by eleven European countries at the start of 1999 and growing to twenty-two by early 2010, with a single monetary policy conducted by the European Central Bank, was intended to eliminate the possibility of such speculative attacks, while leaving the euro

floating against the U.S. dollar, Japanese yen, and other currencies.

International Organizations

Defined in the strictest sense, international organizations count countries and states, not individuals, as their members, and play some official role in the international system, most notably as providers of collective security.

An international organization derives its membership from (or operates in) a number of different countries and plays some official role in the working of the international system. A definitional example of an international organization is the United Nations (U.N.). The U.N. has its own staff, rules, and headquarters; its members are countries rather than people, and almost all countries in the world are members. In the international system, the U.N. was intended to function in several official roles, especially as a provider of collective security.

There is no clear line between what can be considered an international organization and what cannot. Organizations such as the U.N. that are created by treaties among countries and that count countries as their members clearly fit the definition. Multinational corporations and other for-profit enterprises, even though there are ways in which they fit the definition, are generally not considered international organizations as such. Not-for-profit organizations that have individuals rather than countries as their members, often referred to as nongovernmental organizations (NGOs), are in the gray area of the definition. For the purposes of this article, not-for-profit organizations that are clearly international in nature and that play a semiofficial role in the international system, such as the International Committee of the Red Cross, are included in the definition.

War, Peace, and International Organizations

International organizations affect issues of war and peace in a number of different ways. Some organizations are designed to enhance collective security. Others work to prevent conflict by ameliorating some of the conditions that lead to war, such as poverty or ethnic conflict. Still others attempt to alleviate the suffering caused by war once a conflict has already begun. And finally, some international organizations, called alliances, are designed primarily to help their members win wars. The first two categories of activity, collective security and ameliorating the conditions that lead to war, tend to be undertaken by the U.N. and affiliated organizations. The third category, alleviating suffering, is undertaken both by U.N.-affiliated organizations, such as the Office of the United Nations High Commissioner for Refugees, and NGOs, such as the Red Cross. The fourth category, alliances, comprises organizations that are intergovernmental but are not part of the U.N. system.

At this point we should distinguish between collective security organizations and alliances. Alliances consist of two or more countries that agree to aid each other in time of war. This can be a purely defensive arrangement, whereby parties agree to come to each other's aid if attacked by third parties, or offensive, an agreement to attack a third party. Either way, a key feature of an alliance is that it is exclusive, meaning that it is designed specifically to work against the interests of nonmembers. International alliances have been around for millennia; they are, for example, featured prominently in Thucydides's account of the Peloponnesian War in the fifth century BCE.

The “The United Nations Fights for Freedom” poster (1941–1945) depicts the flags of countries that pledged to support the Allies during World War II. National Archives.

But they have traditionally not been organizations as such. They have made agreements, but those agreements have generally not created new special-purpose bureaucracies. The alliance as an international organization is a phenomenon of the second half of the twentieth century, beginning with the creation of the North Atlantic Treaty Organization (NATO) and the Warsaw Pact.

Collective security organizations differ from alliances in that they are inclusive. Such organizations create rules for maintaining the international peace and hold their members to those rules. If a member country breaks the rules in a way that is a threat to international peace, then all of the other members are supposed to take action to counteract the threat. In other words, while alliances aim to defend their members from threats from outside of their membership, collective security agreements aim to defend their members from threats that

originate within the membership. As such, collective security organizations work best the broader their membership. The U.N. was formed primarily as a collective security organization, and the U.N.’s Security Council was designed as its primary enforcement mechanism.

A History of Collective Security

The first attempt at a collective security agreement in the modern state system was the Concert of Europe, an agreement reached in the aftermath of the Napoleonic Wars by the great powers of the time to manage European affairs through annual meetings rather than through alliances and wars. This agreement did not really create an international organization, however, because it did not create a new bureaucratic structure to oversee the collective security system. In any case, the Concert was not terribly successful. By the mid-1820s it had ceased having a major impact on European politics, and by the middle of the nineteenth century had ceased to exist altogether.

The next major international attempt at collective security was the League of Nations, created in the aftermath of World War I. The League was clearly an international organization; it had its headquarters in Geneva, Switzerland, with a permanent Secretariat—its own bureaucracy. The creation of the League was driven primarily by the U.S. president Woodrow Wilson, who felt that a primary cause of World War I had been the politics of secret alliances that dominated European international relations for half a century before the war. He wanted to create an organization that brought countries together to discuss their problems in a public forum, thereby getting rid of closed-door international negotiations. He also wanted to create an organization that guaranteed the peace, thus getting rid of the need for alliances.

The League, like the Concert, was not very successful. It was hamstrung from the outset by the fact that the United States never joined. Despite the fact that President Wilson was the driving force behind its creation, the U.S. Senate did not ratify U.S. membership in the organization. It was also undermined

by its own decision-making structure. The League worked on a one-country, one-vote basis, so a group of small, militarily weak countries that constituted a majority could pass a resolution calling for military action even if the countries voting for the resolution were not strong enough collectively to enforce it. Since the League itself had no military capabilities, it counted on member countries to enforce its resolutions, and those members tended to resort to pass-the-buck arguments—they might want something done, but they wanted some other country to actually do it.

The League did not survive World War II. It was replaced by the U.N., which was created in 1945. The U.N. undertakes a wide range of activities that cover most areas of human endeavor, but its core design function is as a collective security organization. It began with two advantages over the League of Nations. First, all of the major powers were members. And second, it was designed to try to get around the buck-passing problem. The U.N. has a General Assembly that, much like that of the League, passes resolutions by majority vote. But the General Assembly is not tasked to enforce the rules of collective security. In the U.N.'s design, a new body called the Security Council was created for that task. The Security Council has only a few members at any given point in time (originally eleven, now fifteen) and is always in session, so that it can deal with threats to international security quickly and efficiently. The membership includes those nations that were the five greatest military powers at the end of World War II, and it can only authorize the use of force if all five agree.

The U.N. and International Peace and Security

The system never really worked as planned. The U.N. authorized the U.S.-led intervention in the Korean War in 1950, but after that was not able to successfully intervene in Cold War disputes because both the United States and the Soviet Union had a veto in the Security Council. In 1956, in response to the

Suez Crisis, the Security Council invented a new role for collective security, called peacekeeping. This refers to the use of troops authorized by the Security Council to oversee the implementation of cease-fires after conflicts, a more modest role than the enforcement of international security but one that the U.N. has engaged in successfully for decades.

The U.N.'s role in issues of war and peace underwent a renaissance in response to the end of the Cold War around 1990. Freed from the constraints of U.S.-Soviet confrontation, the Security Council was able to authorize more ambitious missions than it had been able to for three decades. These missions, in places like Iraq and the former Yugoslavia, went beyond peacekeeping, and were much like traditional collective security missions. The U.N. also got involved in what came to be called peace building—missions designed to create working political and legal systems in places where the absence of such systems was causing, or was caused by, conflict. Examples of this sort of activity in the 1990s could be found in the former Yugoslavia, in Cambodia, and in East Timor. The renaissance in collective security activity lasted little over a decade. It came to be threatened both by the invasion of Iraq, by increased unilateralism on the part of the United States, and increased foreign policy assertiveness by two other permanent members of the Security Council, Russia and China. The current direction of evolution of the role of the U.N. in matters of international peace and security is unclear.

Beyond Collective Security

The Security Council is aided in enforcing collective security by a variety of additional organizations. Some prevent conflicts by settling disputes by arbitration, such as the International Court of Justice (ICJ). Others are designed to do on a regional basis some of the same things that the U.N. does globally. These include the African Union (AU), the Organization of American States (OAS), and the Organization for Security and Cooperation in Europe (OSCE). These organizations range in age; the OAS was created in

1948, whereas the AU came into being in 2002, although it incorporates organizations that had been created several decades earlier.

The role of international organizations in ameliorating the suffering caused by war goes back as far as their role in collective security. The first such organization was the Red Cross, created in 1863 to help wounded soldiers and oversee the treatment of prisoners of war. Although the Red Cross is a nongovernmental organization, it has a semiofficial capacity in the international system. For example, its role as the monitor of the treatment of prisoners of war is written into the Geneva Conventions on the rules of war. Other ameliorative organizations are intergovernmental, such as the Office of the United Nations High Commissioner for Refugees (UNHCR), which traces its roots back to the appointment by the League of Nations of the first High Commissioner for Refugees in 1921. The UNHCR currently oversees relief efforts to more than 20 million refugees worldwide.

Other international organizations, most of which can trace their roots back to the 1950s, help countries to recover more generally from the effects of war by helping them to develop their economies and basic services; these include the United Nations Development Programme (UNDP) and the United Nations Children's Fund (UNICEF). The efforts of these organizations are augmented by a wide range of nongovernmental organizations dedicated to improving conditions for the most needy internationally.

Outlook on the Twenty-First Century

International organizations have been active for more than a century in promoting international peace and security. The effectiveness of organizations focusing on collective security has varied over time. It increased in general in the decade following the 1991 end of the Cold War, but has waned somewhat since then. The direction of change in effectiveness in the coming decades will help to determine patterns of war and peace in the twenty-first century. The effectiveness

of organizations focusing on ameliorating the negative effects of war has grown consistently, particularly since the end of World War II, and is likely to continue to grow.

Internet

The impetus for computers to communicate grew during the 1950s when the U.S. military sought technologies to protect air space. From the early days of packet switching (a means of bundling separate “packages” of information to transmit them more quickly), pioneers in the field of communications engineered increasingly complex computer networks—resulting in the Internet, used in 2010 by over 1.73 billion people worldwide.

During the 1940s and 1950s, calculators (Electronic Numerical Integrator and Computer, ENIAC) and subsequently computers (UNIVersal Automatic Computer, UNIVAC; Whirlwind) were heavy, imposing, and costly machines reserved for a handful of specialists, and these machines did not communicate with each other. In the space of less than forty years, the world of computing, which was still centralized during the 1960s, entered the public arena and enabled data, sound, and images to be circulated across the globe. This networked information and communication society is embodied by the Internet, a global network interconnecting a growing number of computer networks of all sizes. During the period between the launch of project in the second half of the 1960s by the Advanced Research Projects Agency (ARPA) in the United States (which involved a few American universities) and the growth in Internet users to in excess of 1.73 billion as of 2010, the applications, players, and issues have evolved and taken on a global dimension.

From ARPANET to the Internet: The American Genesis

Even though computing power was a costly element, the need to place this rare resource within the reach

of as many people as possible emerged very quickly in the history of computing. This rationale of maximizing the utilization of machines was rapidly joined by other motivations for connecting computers to each other. From data sharing for management purposes to reservation systems and command and control, the 1950s saw the first developments, particularly in the United States, in networks that put computers in contact with each other—the military naturally leading the way with large-scale projects such as the air defence programme SAGE (Semi-Automatic Ground Environment). The goal of this program was to give the U.S. Air Force a system that would enable it to detect, identify, and intercept any air threat to U.S. territory. To achieve this, a range of devices, radars, computers, planes, and vessels needed to be connected via a telecommunication system using telegraphic and radio-relay links. The SABRE (Semi-Automatic Business Research Environment) airline reservation system was also, between the 1950s and 1960s, an essential stage in this evolution, demonstrating the myriad possibilities that these networks offered for commercial activities. These systems incorporated the notion of “time sharing” (which allowed computers to process tasks in less time, users to access computers directly without necessarily going through an operator, and a more “interactive” form of computing), but they went beyond this to deliver a highly innovative usage of computing. They ushered in the era of On Line Transaction Processing (OLTP) and the use of devices for accessing a complete network of computers.

Occupying a middle ground between telecommunications and computing but primarily developed by computer scientists, new concepts emerged between the 1950s and 1960s. This was the case with packet

ARPANET LOGICAL MAP, MARCH 1977

ARPANET logical map, circa 1977. The goal of the ambitious ARPANET project was to build a network of computers based on packet switching.

switching (dividing messages into packets, transmitting the packets individually, and reassembling the messages when they arrived at their destinations), of which three strands can be identified. The first is a military concern and is found in the work of Paul Baran, who from 1959 at the Rand Corporation studied the possibility of creating a communication network incorporating redundancies that would make it virtually immune to enemy attacks. To this end, he proposed a project to the U.S. Air Force based on the digitization of information and its transmission in blocks or packets of information of an identical size. The project was never carried out, but the ideas on which it was based were nevertheless fairly widely disseminated. Professor Leonard Kleinrock was at the same time working independently on a network architecture. In July 1961, while at the Massachusetts Institute of Technology, he published a paper on packet switching

theory, followed by a first book on the subject in 1964. Shortly thereafter, Donald Davies of Britain's National Physical Laboratory (near London) devised a project that was technically fairly similar in its concept but focused on interactiveness rather than security; he developed a packet switching network project beginning in 1968. These ideas found their way into the project developed at the Advanced Research Projects Agency (ARPA) from the end of the 1960s. This agency, created in 1958 against the backdrop of the Cold War, was a response to a double challenge—externally, the space race (launch of Sputnik by the Russians in 1957) and, internally, the reorganization of military research.

Going much further than what was envisaged under the SAGE program, the agency planned the creation of a Command and Control network, which was officially approved in the spring of 1967. The aim was to implement a network allowing the interconnection

of incompatible computers and software. At the end of 1967, ARPA concluded its first contract with the Stanford Research Institute to define the future network's specifications. Elmer Shapiro was the main architect behind this. Lawrence Roberts took charge of the project at ARPA within the Information Processing Techniques Office. In 1968, the Network Working Group was founded, the first director being Stephen Crocker, and a fully-fledged team was formed to create the ambitious ARPANET project to build a network of different computers based on packet switching. Pioneers in the field of networks such as Leonard Kleinrock, former colleagues of Lawrence Roberts at UCLA, and several students, including Vinton Cerf and Jon Postel, contributed to its creation. Robert Kahn entered the picture in 1968 through Bolt, Beranek, and Newman (BBN), a consulting firm based in Cambridge, Massachusetts, which won the contract with ARPA to create IMPs or Interface Message Processors, which made communication between different computers possible. In 1969, the network already had four connections between universities in the United States, the first being established with UCLA, the other centers being the Stanford Research Institute; the University of California, Santa Barbara; and the University of Utah.

The program strongly emphasised the twin benefit of the initiative: creating a full-scale test of what a computer network could be and, at the same time, giving university laboratories and the military a tool that was already pre-operational. The annual budgets ran into several millions of dollars. Although, following a call to tender (for contracts) the development of links between the various centers was entrusted to BBN, issues pertaining to communication between the centers and the network were specifically tackled by the centers. Academics were very closely involved in defining the network. In the summer of 1968, Elmer Shapiro held a seminar attended by the programmers of the various centers due to connect to the future network. This would prove decisive. Because the project did not have to factor in any pre-existing network infrastructure, the researchers attending were able to engage in highly innovative approaches

and start work on a practically blank page. An extensive theoretical approach therefore became a part of the debates, not out of scientific "ambition" but simply as a way of laying the foundation for a radically new field. The Request for Comments (RFC) is testament to the researchers' creativity. This was initially comprised of meeting notes. After their formalization by Steve Crocker in 1969, they were distributed on paper, and then made accessible online following the creation of File Transfer Protocol. The RFC were released to speed up exchanges of ideas and create a system of "open documentation" and works in progress.

Progress would thereafter prove fairly rapid, with the first major test successfully conducted in October 1971 during a meeting held at MIT. Just over four years after its launch, the project, now called ARPANET, had reached its goal. In 1972, the International Conference on Computer Communication saw the first public demonstration, organized by Robert Kahn. In 1974, together with Vinton Cerf, Robert Kahn published an article that defined a protocol with a decisive role in the history of the Internet, TCP, which would then become TCP/IP (Transport Control Protocol and Internet Protocol) and replace the first protocol of ARPANET, NCP (Network Control Program). The idea was to be able to connect and allow communication between numerous independent networks featuring a different design, and even radio or satellite networks using packets, which NCP did not allow, thus paving the way for the "network of networks".

TCP/IP was not introduced at ARPANET until 1983. The military portion then separated from the network and was called MILNET, while the university portion took advantage of research efforts by the National Science Foundation to connect its powerful computers there and merged with the NSFnet network before calling itself Internet.

European Initiatives

European researchers did not remain isolated from the explorations into general networks and packet

switching from the beginning of the 1970s. They felt that general networks could act as an alternative faced with the risk of the U.S. industry, particularly IBM (International Business Machines), taking a stranglehold on the European market and on data networks. By offering network architectures that only supported their own machines (Systems Network Architecture by IBM, Decnet by Digital Equipment Corporation, etc.), manufacturers restricted the ability of users, administrations, and businesses to connect machines made by different manufacturers. Incorporating a variety of machines into networks, as ARPANET proposed, emerged as a way to secure a place for computers made by national manufacturers alongside the U.S. industry's machines. The intention was also to prevent a gap widening between the U.S. and European countries in research and in a cutting-edge sector with promising prospects. ARPANET's demonstration in 1972 meant that the Americans were joined by researchers from the other side of the Atlantic such as Donald Davies of NPL and John Wedlake of British Telecom; Remi Després from the telecommunications world and Louis Pouzin of the National Institute for Research in Computer Science and Control (IRIA) in France; and Italy's Gesualdo LeMoli and Kjell Samuelson of the Swedish Royal Institute. The French and British were heavily involved in initial explorations in packet switching. Experiments were set up during the 1970s both in research centers that focused more on computing (the NPL's Mark I or Cyclades at IRIA) and telecommunications laboratories (Experimental Packet Switching Service at the British Post Office, Transpac in France). In 1971, the ARPANET network had already linked fifteen centers in the United States when the Cyclades project was launched at IRIA (later to become INRIA, Institut national de recherche en informatique et automatique) under the supervision of Louis Pouzin. During the 1970s, his team developed a general network based on the principle of datagrams, which were included in the TCP/IP protocol in 1974. The team submitted proposals as part of the International Network Working Group headed by Vinton Cerf and also had direct dialogue with the ARPANET team (consulting

contract with BBN for example). Meanwhile, in 1973 the British completed a link between the ARPANET network and University College of London, thanks in particular to the efforts of Peter Kirstein.

Alongside national efforts, from the 1970s the Europeans teamed up to implement transnational networks such as European Informatics Network and Euronet, and their studies intensified during the 1980s, resulting in the creation of a bona fide network of European researchers. At the time there, however, was a divide between the world of computing and the world of telecommunications, which instead of datagrams preferred a technique based on virtual circuits (X25 protocol adopted in 1976), as well as a search for separate national solutions (JANET in the United Kingdom, DFN in Germany, SURFNET in the Netherlands, etc.). Nevertheless, in the mid-1980s, European researchers came together with the aim of adopting the OSI technology. Work on the Open System Interconnection began in 1977 at the International Organization for Standardization (ISO); its seven-layer model for a general network was officially adopted in 1984, but the program was abandoned during the 1990s. Although from 1986 the Europeans proposed creating a European research infrastructure called Cosine, based on OSI, in 1990 they had to acknowledge the effectiveness of TCP/IP, at a time when the Internet was growing in Europe thanks to the EUNET network. Since 1988, this had drawn on the Unix operating system and TCP/IP, and its main partners in Europe were the Royal Institute of Technology in Stockholm, the National Research Institute for Mathematics and Computer Science in Amsterdam (CWI) and France's INRIA. At the same time, experiments were conducted into telematics aimed at the general public (Prestel in Britain, Bildschirmtext in Germany); the dissemination of these interactive systems could have been extensive and enduring, as shown by the Minitel technology developed by the French telecommunications administration. But some national networks had already adopted the Internet technology, including Scandinavian countries and the Dutch network SURFnet. From 1988, a European nonprofit organization called

Cords = connectivity: wires plug in to an Internet hub. Photo by Daisy Durham.

Réseau IP Européen (RIPE) was tasked with allocating Internet addresses in Europe. The following year, Europe was the stage for an innovation that became decisive for the growth of the Internet: the creation of the World Wide Web. Although the Internet and one of its most famous applications should not be considered one and the same, the invention of the Web marked a turning point. Its history began in 1989, when Tim Berners-Lee, a researcher at CERN (European Organisation for Nuclear Research) in Switzerland, had the idea of creating operating software that was adapted to researchers' needs in order to create a hypertext documentation system. The software that enabled the navigation known as World Wide Web was ready at the end of 1991, while browsers such as Mosaic by Marc Andreessen (of the University of Illinois), Navigator by Netscape, and Internet Explorer by Microsoft were in development. In 1994, the World Wide Web Consortium (W3C)

was created at the Massachusetts Institute of Technology. France's INRIA was the European host of the W3C in 1995. One of its researchers, Jean-François Abramatic, became its chairman from 1996 to 2001, before taking up a position in 2003 at the ERCIM (European Research Consortium for Informatics and Mathematics), which comprised representatives from around thirty European countries. The Internet then made the transition from a network of researchers to a public network and, at the start of the twenty-first century, there were already more than 105 million European Internet users, albeit slightly fewer than in the United States.

A Global and Public Expansion

During the 1990s and even more so during the 2000s, the Internet set out to win over a public owning an ever larger number of personal computers,

The Internet is becoming the town square for the global village of tomorrow. • **Bill Gates (b. 1955)**

and its growth reached every region of the globe. Although the Web directed the Internet towards the general public, other applications helped its expansion, such as the success of emails (from 1975 ARPANET had around a thousand email addresses and the first version of SMTP, Simple Mail Transfer Protocol, was proposed by John Postel in 1982) and the huge success of a retail space on the Internet at the end of the 1990s. Sites such as eBay and Amazon contributed to the e-commerce boom; in 1998 the Geneva agreements confirmed the initiative backed by U.S. president Bill Clinton stating that customs duties should temporarily not apply to commercial transactions conducted on electronic networks. The organization of information searches, ranging from the service provided by Netscape, to the Google model, and portals—Yahoo!, AOL, MSN—also played a key role. The stock market flotation of Netscape in 1995, followed by other start-ups (eBay, Amazon) and the increase in the value of the NASDAQ (technology shares) marked the end of the 1990s, before the speculative bubble burst in 2000 (stock market crisis).

More recent applications have altered both usages and the Internet model. In 1999, fostered by broadband and emerging alongside Napster, was the deployment of peer-to-peer (P2P, a class of applications dedicated to the sharing of resources between peers). P2P offers a mode of operation different to that of the client-server model: the data exchanged are spread across the machines of all participants; each person can download files from any machine connected to the network and make their own files available to others.

The popular uses have overshadowed the organizational and technical aspects and the words “Internet” and “Web” are often used without distinction. For most people, the Internet is about surfing the Web, sending and receiving emails, using search engines like Google, and reading and writing blogs and wikis, being a part of social networks like Facebook (the world’s largest social Networking website, founded in 2004) and Youtube (a video sharing website, founded in 2005), and participating in e-commerce.

The indexed Web contains at least 8.06 billion web pages, Facebook more than 350 million active users in 2009, and nomadic access is also developing, re-considering Internet mobility.

Internet applications often raise issues of a legal nature regarding liability law and the handling of personal data and intellectual property, which are made more complex by the fact that the network is deployed globally. Security issues linked with the problems of spam and cybercrime are also a concern. Aside from these factors, two themes are currently drawing the international community’s attention: the digital divide and Internet governance. The International Telecommunication Union has highlighted its aim to “connect the unconnected by 2015” and to “achieve equitable communication for everyone.” Indeed, whereas Internet penetration in 2009 totals nearly 75 percent in North America and 50 percent in Europe, the figure is less than 7 percent in Africa. Nearly half of the world’s 1.73 billion or so Internet users are of a North American or European origin and just 65 million are Africans, according to the uppermost estimates.

Alongside these international imbalances in Internet access and usage, a call was made at the World Summit on the Information Society (Geneva 2003, Tunis 2005) for Internet governance to be less dominated by the United States. The 1990s were a period of major upheaval in the organization of the Internet and growing complexity in the players and parties involved; this included the creation of the Internet Society in 1992 and the creation of the World Wide Web Consortium in 1994. By expanding, the Internet infrastructure diversified and gradually saw a multi-division organizational structure take shape. The notion of governance has been enriched due to a range of factors, including the creation of the ICANN (Internet Corporation for Assigned Names and Numbers) by the United States in October 1998 to handle issues relating to the management of domain names, the creation of the Working Group on Internet Governance at the WSIS in Tunis (November 1995), and then the Internet Governance Forum, the World Human Development Report in 2001 by the United Nations Development Programme, the World Information

Technology Program in 2003, and debates on IPv6 (a new generation of Internet connectivity that extends addressing possibilities to near-unlimited proportions). Issues include such diverse questions as multilingualism, domain names, the use of free software, values and ethics, and freedom of opinion and speech—all global challenges in the twenty-first century. Obtaining access to the Internet on a non-discriminatory basis fosters everyone's fundamental right to communicate, thus enabling a move from a mere "information society" to a democratic society in which access to knowledge and communication are universal.

Interregional Trade Networks

Prolonged and frequent contact between different parts of the world through trade has been a consistent part of world history since the establishment of Phoenician routes and the Silk Roads in ancient times. In the twenty-first century global economy trade in capital, labor, and merchandise is the most obvious manifestation of interregional networking, but similar phenomena exist in the cultural realm.

While the term *globalization* suggests itself as a relatively new phenomenon, global history may be understood as a succession of prolonged and frequent contact between different parts of the world. One way of thinking about these global relationships is through the metaphor of networks. Networks are arrangements of connections into nets, or permeable systems linking groups of points and intersecting lines. Obvious examples are the body's circulatory system—a network of veins and arteries—or a country's transportation network of roads, railways, rivers, and canals. Global interregional networks are defined by a complex series of interactions, such as trade and communications, which span relatively wide geographical areas.

Interregional networks have two important characteristics in common. The first is the distance between the various points of the network, a condition that makes a sophisticated set of governing and logistical structures necessary. These structures naturally reflect and may encourage the social development of the parties involved. The second critical aspect of such connections is that they are not transitory, but go on for a relatively long time and come to achieve a certain predictability. We therefore understand interregional

networks to be complex structures for maintaining a semipermanent connection between two or more points across great distance. Trade has been a catalyst for such networks since early times.

Early Networks

Enough evidence exists of prehistorical trade—in obsidian, for example—to indicate that some fairly far-flung exchange relationships had evolved by the fifth millennium BCE. The first example for which we have extensive evidence has its center in the eastern Mediterranean in the second millennium BCE. Cultures in this region appear to have engaged in the importation of materials such as tin, amber, and lapis lazuli, possibly from as far away as Britain and Afghanistan. In addition to trade, massive migrations were creating diasporic communities throughout the region. By 800 BCE, the Phoenician trade network ranged from contemporary Lebanon to Gibraltar and possibly beyond. There is much less evidence for interregional connections in the Western Hemisphere during this period, such as between Mesoamerica and the Andes, or even between the river civilizations of Indian and China; it is unclear whether the spread to Central Asia of Indo-European languages and cultural artifacts like chariots reflects an ongoing exchange or simple unidirectional conquest. The conquests of Alexander of Macedon (Alexander the Great, 334 BCE–323 BCE), however, certainly created a medium-term network.

By the beginning of the Common Era, there had grown up a complex set of interregional exchanges across most of Eurasia. Spices imported from as far

Alberto Pasini, *The Traders* (c. 1870s). Oil on canvas. The painting, an icon of late-nineteenth-century Orientalism practiced in the West, depicts an Arab caravan on the Silk Roads network.

away as Indonesia appeared on tables in Rome. The Roman Empire was sustained by a set of regional exchanges facilitated by Rome's hegemony over the Mediterranean and its creation of an excellent road network. The famous Silk Roads stretching from Han China to Constantinople and Alexandria was already well established by 500 CE.

Medieval Networks

At least for the European peninsula, many of these networks were broken by the early Middle Ages. Two prominent exceptions may include the network of Viking settlements ranging from the Volga to Newfoundland and the pilgrimage routes and other connections between relatively isolated monasteries. Only in the twelfth and thirteenth centuries do we see the reestablishment of a cross-Mediterranean network, largely managed by Italian city states. Of even greater historical import is that this period sees the development of a true network of markets in central Europe, bounded to the east and west by the Rhine and Seine rivers, and to the north and south by the North Sea and the Alps. The desolation of the Black Death of 1347 to 1352 serves as the best indication of the reconnection between European regions and between them and the rest of the world, reflecting that

networks can transmit a multitude of things, not all of them welcome.

In Africa, this period marks the highpoint of the Sahara as a desert "ocean" bearing significant trade. Multilateral trade in gold, salt, and other commodities interconnected the Mediterranean coast with the Gulf of Guinea and the Atlantic with the Red Sea. A perhaps even better-developed network allowed the transfer of goods, people, and information from the Mozambique Channel northward along the African coast and across the Indian Ocean (arguably the locus of international trade during this period). To this largely mercantile network we need to add the variety of connections fostered by the Islamic conquest begun in the seventh century. From the southern Spanish kingdom of Granada (until 1492) to the Pacific island of Java (by the end of the fifteenth century) a shared faith expressed in the Qur'an and through the Arabic language provided a base for a multitude of links, despite the fractionalization of political power. These connections and commonalities would arguably make the Muslim world of this period the first truly globalized society. To a somewhat lesser degree, the Mongol Empire of the thirteenth century created a single Eurasian entity and promoted considerable long distance exchange and interaction.

President William Clinton and Vice President Albert Gore meet with environmental groups endorsing the North American Free Trade Agreement, 14 September 1993. National Archives.

Modern Networks

The European discovery of the Americas marked a new stage in the development of interregional networks. Even prior to 1492, the Portuguese had created a direct link between South and Southeast Asia and the Mediterranean. With the advent of the annual Spanish silver fleet from Manila, international connections become trans-oceanic. But this was merely a part of a global network of exchange that took spices and silk from the east, timber and grain from the north, sugar, coffee, cotton and tobacco from the west, and slaves from the south, and combined them for reshipment from the warehouses along the North Sea. The slave trade is perhaps the best example of the kind of interregional network created in the new imperial age. The foundation of this trade was a complex set of exchanges within the African continent that helped shape the economy, politics, and demographics of the region for centuries. To these were linked the new manufacturing centers of northwestern Europe needed to make the ships and the manufactured goods exchanged for the human cargo. After crossing the Atlantic, this same cargo produced the tropical commodities that would go back across the Atlantic to begin the process again. While the Atlantic Ocean dominated trade during this period, land networks did persist in the Ottoman and Safavid empires in the Asian subcontinent and in East Asia. By the nineteenth century, however,

Europeans had come to completely dominate all interregional networks.

As noted above, networks exchange more than just merchandise: cultural ideas and phenomena also cross between regions, leading to new assimilations, combinations, and sometimes conflict. Migrations were also a significant part of these networks. An estimated 40 million Europeans crossed the Atlantic between 1600 and 1900. At least 20 million Africans were forced into slavery (including several million moving eastward). The Indian diaspora reached every continent, as did the much larger migration from China (over 20 million in the nineteenth century alone).

In the twentieth century, significant numbers of inhabitants of former colonies have moved to the lands of their former colonizers, creating a dense network of familiar visits, business contacts, and remittances. Contemporary global interregional networks retain significant legacies from this imperial past. Thus, airline and telecommunication networks in Africa tend to be divided between those centered in London and those in Paris. In many cases, these imposed network connections and attendant specializations make it difficult for weak economies to grow. Most famously studied in the case of the external financial and commercial asymmetries in the relationship between Latin America and Europe and North America as described in *dependencia* theory, we can also see the consequences of such

phenomena in the challenges to the development of the former Soviet Union.

Obviously, contemporary interregional networks also have significant advantages. Perhaps the clearest example is the creation of the European Common Market and later the European Union, which accounts for two-thirds of the trade of all the associated nations. The East Asian region has created a similar series of linkages within the Association of Southeast Asian Nations (ASEAN), but here national sovereignty remains more sacrosanct. The only other example that has approached this level of success is the North American Free Trade Agreement, but the centrality of the United States makes this much less of a network than the unification of three economies; we see less an exchange between equals and more the monopoly of a single node. These three regions (Europe, North America, and East Asia) also make up the vast majority of exchanges among global regions.

While the international trade in capital, labor, and merchandise is the most obvious manifestation of interregional networks, similar phenomena exist in the cultural realm. The required hajj, or pilgrimage to Mecca, has created an extensive network of logistical support across the Islamic world. More prosaically, the combination of migrations and international sales has created often strange networks of cultural

products including India's Bollywood movies, Brazilian soap operas, and American action epics.

Interwar Years

(1918–1939)

Despite hopes and expectations for a new era based on greater freedom at home and greater collaboration abroad, World War I left a legacy of wounds, ambiguities, and unresolved disputes. During the 1930s, conflicts between empires and colonies, democracy and authoritarianism, and nationalism and internationalism played out on a world stage, and by 1939 sparked a second world war even more destructive than the first.

World War I—the “Great War” that had mobilized both human and material resources on a global scale—created during the interwar years (1918–1939) a general disillusionment with the hierarchical and European-centered nineteenth-century political order. The liberal dream of limitless scientific and technological progress had led to the development of weapons that had killed 7 million soldiers and civilians and had wounded 13 million others. The German writer Oswald Spengler’s *The Decline of the West* cited the war as evidence of the West’s imminent deterioration. Furthermore, colonized populations across the globe began to question the supposed “Western superiority” that European nations used to justify their imperial policies. Consequently, although world public opinion clamored for peace and stability, people had a strong sense that a simple return to the antebellum belle époque (beautiful age) was not the most desirable solution.

Even if some people wanted to restore the bourgeois sociopolitical structure that had existed before 1914, that restoration no longer seemed possible. The mass mobilization, mass production, mass consumption, and mass culture that

the war had generated also helped replace the elitist nineteenth-century system with mass societies and mass politics. Throughout the war men and women alike had felt increasingly invested in political affairs, both because of the sacrifices they had made and because the popular press had kept them constantly informed about the war’s happenings. Moreover, knowing that an increasingly global audience relied on the media to provide information and answers, politicians had begun using the media to spread propaganda and garner support. Leaders from every end of the political spectrum had made public promises about what “the people” could expect or demand when the war subsided. After the Russian Revolution the Russian Communist leader Vladimir Lenin (1870–1924) had called for the workers of the world to unite to conquer the forces of capitalism. The U.S. president Woodrow Wilson (1856–1924), on the other hand, had promised that when the fighting stopped all those who participated would be able to enjoy greater equality, freedom, democracy, and national self-determination.

Thus, as the war was winding down, people were gearing up to inherit a better world. However, people had multiple and often contradictory ideas about what the new world order should look like. In addition to ideological disagreements among Communism, liberal democracy, and a burgeoning neo-conservatism, people everywhere rallied for expanded suffrage, shorter work days, higher wages, and the right to transform ethnically organized or imperially occupied territories into sovereign nations. Furthermore, whereas many voices spoke out against the technology that had made

the war possible, more people than ever clamored for a share of modernity's amenities, such as the radio and the automobile. When the armistice finally came on 11 November 1918, the French prime minister, Georges Clemenceau (1841–1929), announced “we have won the war, now we must win the peace.” As Clemenceau predicted, the task of restoring order was to be incredibly difficult, and after the guns fell silent many thorny issues remained unresolved.

In January 1919 the Paris Peace Conference convened to decide the fate of the vanquished aggressors (Germany, Austria, and Turkey) whose empires the war had toppled. One year earlier—on 8 January 1918, to the U.S. Congress—Wilson had delivered his Fourteen Points, which provided the structure for a more equitable system of international relations based on international law and protected by an association of independent nations that would cooperate to maintain order. Although the desire for peace and international cooperation was fairly widespread, and Wilson's role at the Paris Peace Conference was prominent, most delegates tried to push the settlement in a direction that optimized their own national interests. Despite Wilson's continuing insistence on the universal right of self-determination, the Allied powers (Russia, France, England, Italy, and the United States but especially France and England) emerged from the peace settlement with more territories than ever before. The vast spoils included oil fields in the former Ottoman Middle East and mineral-rich territories in what had been German East Africa. To appease Wilson, the victorious powers had agreed to manage the territories as “mandates” until they were ready to govern themselves rather than simply annexing them.

Unrest and Revolt

The Treaty of Versailles and the League of Nations—the intergovernmental organization that Wilson envisioned—went into effect on 10 January 1920. But even before the treaty was officially signed,

This 1918 Belgian poster by P. A. Masui-Castrique—depicting a man, woman, and child looking at ruins of a town—expresses Europe's disillusionment with the hierarchical nineteenth-century political order. Library of Congress.

dissatisfaction, malaise, and revolt emerged all over the map. Following in the footsteps of the Russian Revolution (whose leaders thought the League of Nations was a bourgeois sham), revolutionary politics were brewing in Hungary under the leadership of Bela Kun (1835–1939), in Bavaria under the leadership of Eugene Levine, and in Germany under the leadership of Karl Liebknecht (1871–1919) and Rosa Luxemburg (1871–1919). Labor and/or race riots broke out in Bolivia, Brazil, Argentina, and the United States, while Mexico was locked in a civil war that had begun in 1910. Furthermore, fear of the socialist call for worldwide revolution spurred counterrevolutionary forces, and informal armies or vigilante groups set out to take revenge on left-wing activism in the name of nationalism.

Revolutionary activity and social unrest were taking place in southern and eastern Asia. On 13 April

1919, Indian civilians were protesting British policies at Amritsar in Punjab when the British general Reginald Dyer ordered soldiers to fire on the crowds, killing 379 Indians and wounding 1,200. After hearing that the Versailles Treaty awarded Germany's concession rights in the Shandong Peninsula to Japan, thousands of Chinese students demonstrated in Beijing and continued to boycott Japanese goods. In the midst of all this political unrest, an influenza epidemic was circling the globe. It spread via trade routes, and outbreaks occurred in North America, Europe, Asia, Africa, Brazil, the South Pacific, and in India, where the mortality rate was particularly devastating. The epidemic only intensified the sense of worldwide unease.

Despite such unease, in many ways the Treaty of Versailles and the establishment of the League of Nations were a great victory. They filled the advocates of internationalism with hope that peace through disarmament and cooperation might yet be possible. But the peace left nearly as many loose ends as the war. The harsh reparation terms that the peace inflicted upon Germany, along with the contentious ways that it had accorded statehood to some territories and denied it to others, all but guaranteed that further contention would accompany efforts to create international stability. People widely felt that the treaty had not granted many people the recompense they desired for the losses they had suffered. Woodrow Wilson could not get even his own country to agree to the treaty's terms; on 19 March 1920, the U.S. Senate failed to ratify the Treaty of Versailles and in doing so refused to participate in the League of Nations. This shocking event did not augur well for the fate of the Fourteen Points and the world that Wilson envisioned.

Despite the absence of Germany, Russia, and the United States the League of Nations set about fulfilling its aims and functions. In 1921–1922 a conference in Washington drew up a naval treaty limiting the capital ships of Britain, the United States, Japan, France, and Italy. Furthermore, a conference on disarmament met in Genoa in 1922,

and in 1925 in Locarno, Switzerland, treaties were drawn between Britain, France, Germany, Italy, and Belgium guaranteeing the western European boundaries against violation. However, while the Europe-led League of Nations was trying to “make the world safe for democracy,” nations and peoples both in Europe and beyond continued to search for alternatives to liberal democratic Wilsonian ideals.

By 1923 Marxism's revolutionary threat had been greatly reduced. However, people still feared it enough to bring fascism to power in Italy in 1922 and a military dictatorship to Spain in 1923 and to renew the Nationalist Socialist Party (which would become the Nazi Party) in Germany in 1925 after Adolf Hitler (1889–1945) was released from prison. Fascism began to appear as a “third way,” an alternative between the poles of Communism and democracy. As fascism was on the rise in Europe, colonized populations elsewhere grew even wearier of the imperial double standards that offered freedom and democracy at home but oppression abroad. To combat European liberalism's numerous contradictions, anticolonial forces began to claim various forms of nationalism for their own.

Anticolonialism

In Kenya, where colonialism was fairly recent, Harry Thuku began demanding that the British simply provide better education and return the lands they had seized from the natives. He was arrested by the British in 1922. In India an outright anticolonial nationalist movement was under way. Throngs of Indians followed the leadership of Mohandas Gandhi (1869–1948), who instigated a campaign of nonviolent resistance (*satyagraha*) in 1922 to attain self-rule (*swaraj*). In Egypt an elite Egyptian politician asked to be invited to the peace conference at Versailles so that he could present his case for independence from Britain. When he arrived, however, the British arrested him. The incident led Egyptians

to revolt, which gained them partial independence by 1922.

In 1926, in an act of good faith, the League of Nations invited Germany to join. Furthermore, in 1928 the French foreign minister, Aristide Briand (1862–1932), and the U.S. secretary of state, Frank Kellogg (1856–1929), initiated a pact to exclude war as an option in foreign policy except in self-defense. Sixty-five nations met in Paris to sign the Kellogg-Briand pact. The Kellogg-Briand pact was a tremendous accomplishment, to be sure; however, the fault lines of the period ran deep. Britain, for example, agreed to sign the pact only as long as Britain could use force within its own colonies. The conflicts that raged throughout the 1930s were not dissolved in Paris in 1928. In fact, they were on the verge of deepening in the face of the devastating economic depression that was just around the corner.

On 29 October 1929 (Black Tuesday), the U.S. stock market crashed and sent shock waves throughout the world economy. By the mid- to late 1920s the consumerism of the “jazz age” that had led to greater production had begun to decline, and prices had begun to fall. Furthermore, wobbly governments deeply indebted from the war and small investors had begun to default on their loans from the United States. As a result federal managers raised interest rates, and financial institutions began to collapse. The panic spread to the world market, where investors had been investing in speculative ventures for a quick profit. The crash led to the rise of tariff borders and hence a contraction in world trade. Everywhere people suffered from unemployment and hunger. The depression caused people to further question the liberal doctrine of free markets, and states began to intervene more heavily in economic affairs.

To many people U.S.-style laissez-faire democracy (opposing governmental interference in economic affairs) seemed to have failed to provide the prosperity it had promised, and people began welcoming authoritarian solutions to poverty and mass unemployment. Soviet Russia, fascist Italy, Nazi Germany, and militaristic Japan mobilized against

the liberal democracies whose “moral decay” and “decadence” they claimed to overcome. Leaders such as Joseph Stalin (1879–1953) of the Soviet Union, Benito Mussolini (1883–1945) of Italy, and Adolf Hitler of Nazi Germany promised to deliver all of modernity’s benefits without side effects such as class division, urban-industrial squalor, or moral and social decay. In order to enact their programs, however, the authoritarian leaders of both the right and the left first identified scapegoats upon whom they could place the blame for the adverse economic and social conditions, and then they advocated violence to dispense with their “enemies” in the name of national progress. Stalin identified the “wealthy peasants” as the primary enemies of the state and proceeded to intern them in work camps. The Nazi Party blamed Jews for all of modernity’s evils. Hitler railed against both “Jewish capitalism” and “Jewish bolshevism,” and when he came to power in 1933, he immediately devised a number of plans to take care of the “Jewish problem”—plans that would lead to the Holocaust.

By the mid-1930s the international order created by the treaties of Versailles, Washington, and Locarno was in a state of decline, and nations everywhere began the process of rearmament. In Spain a civil war (1930–1939) raged between the left and the right. Furthermore, in defiance of the Kellogg-Briand pact Mussolini invaded Ethiopia in 1931, Japan invaded Manchuria in 1932, and the League of Nations stood by helplessly. By 1936 Hitler sent soldiers to occupy the Rhineland, and by 1938 Germany had absorbed Austria. Wanting to avoid repeating the horror of World War I, France and Britain sought a peaceable solution with Germany and made several concessions to Hitler, a solution that people have called “appeasement.” At a conference in Munich in 1938 Hitler received the Sudeten territories; however, in defiance of all agreements he invaded Poland on 1 September 1939. By 3 September the world was once again at war.

Despite all the expectations that people had for a new order based on greater freedom at home and greater collaboration abroad, World War I had left too

many wounds, ambiguities, and unresolved disputes. During the 1930s the conflicts between empires and their colonies, between democracy and authoritarianism, between nationalism and internationalism played out on a world stage. By 1939 these conflicts seemed destined to be resolved by yet another war, a world war that would be even more destructive than the first.

Once humans learned how to refine it, iron became the preferred metal for making both tools and arms. Cheap and strong, iron played key roles in the development of society in both Asia and Europe. Iron is the key component of steel, which remains an important manufacturing material for both civilian and military products.

Iron is Earth's most common element. The planet's core is made of molten iron, and about 4 percent of the Earth's crust is made of iron combined with oxygen to form other chemical compounds. When humans learned how to refine it, iron quickly became the cheapest material for making weapons, armor, and tools. Together with steel—a mix of iron with small amounts of carbon and other elements—iron remains the most common metal, used in innumerable ways in heavy construction and the manufacture of machines, weapons, everyday tools, and household equipment.

In their solid state, iron atoms can form several different crystal structures, each with its own characteristics. Small impurities, especially of carbon, also affect iron's hardness, flexibility, melting point, magnetism, and propensity to rust. For centuries, chemists did not know why iron was so diverse. Nevertheless, foundries, where different iron ores were converted into useful forms of the metal, developed rules of thumb for obtaining desired results. Iron smiths and smelters liked to keep trade secrets to themselves.

A New Metal

High temperatures (1540°C, or 2800°F) are required to separate iron from its ores. By learning how to build furnaces that created natural drafts of air, often assisted by bellows, and by using charcoal as fuel, smelters created high enough temperatures to approach the melting point of iron in Cyprus and eastern Anatolia by about 1400 BCE. Two hundred

Panoramic photograph of a mountain iron mine in Minnesota, circa 1902. Library of Congress.

years later, iron smelting had spread to neighboring regions, and the scale of production had increased sufficiently that historians habitually speak of an Iron Age succeeding the Bronze Age when that more expensive metal had supplied ruling classes in western Asia and distant China with arms and armor. Iron smelting reached China by about 700 BCE, and itinerant blacksmiths and smelters soon carried their skills across all of Eurasia and much of Africa, but native Australians and Amerindians did not know the use of iron until European explorers introduced it after 1500.

In western Asia and adjacent regions where the use of iron first became common, the new metal had two principal effects. First of all, iron was far cheaper than bronze, so greater numbers of infantrymen could be outfitted with swords, spearheads, helmets, and shields to protect them more effectively from the arrows of charioteers. As iron-clad infantry became decisive in battle, chariot-led armies were overthrown everywhere. In Greece, and subsequently in Italy, a more egalitarian society emerged; ordinary farmers equipped themselves with iron armor and weapons and then learned how to keep in close formation behind an unbroken shield front and charge against less well-organized foes, thus sweeping them from the field. Classical Greece and republican Rome achieved a distinctive military form, in which armed citizens used spears and swords to defend city-states.

In western Asia, by contrast, far larger empires persisted, relying on professional armies of cavalry and infantry who continued to use bows for attacking from a distance.

The other effect of cheap iron was that iron hoes and plowshares became available to more and more cultivators. That made plowing and weeding easier, quicker, and more efficient, increasing the harvest. This allowed a majority of people to participate in the market for the first time, selling part of their harvest to buy iron tools that could last a lifetime. As farmers came to rely on iron tools they became marginally dependent on the specialists who dug iron ore, smelted it, and then cast or hammered the iron into shape. Also important were those who transported the ore, iron, and tools from place to place and from specialist to specialist during the complex process of production and distribution. Everyone benefitted when that process went smoothly, and wealth increased.

Subsequently, supplies of iron enlarged from time to time, and new tools, armaments, and conveniences for ordinary consumers became available in more and more places. Civilized forms of society spread within Eurasia accordingly and interdependence tended to increase. To be sure, iron supply was only one element in forwarding that course of events but was always important both for civilian and military affairs.

Iron in Asia

The first major documented surge in the scale of iron production took place in China, where tax records show that new, far bigger furnaces using coke (a coal derivative) for fuel raised output from 32,500 tons per year in 998 to 125,000 tons in 1078. This almost four-fold increase in eighty years centered in the provinces of Henan and Hubei in northern China, where beds of iron ore and coking coal lay close together. Who mined the ore and coal, made the coke, and managed the furnaces remains unknown. The imperial government played a dominating part, setting out to monopolize the distribution of iron tools to farmers and deriving significant income from keeping prices high. The government also commandeered vast quantities of iron for manufacturing weapons, constructing bridges, and making coins. Scattered records mention a single order for 19,000 tons of iron to make into coins and refer to arsenals that turned out 32,000 suits of armor in a single year.

This attests to the scale of government consumption and supervision. Disaster soon followed, but no record survives to tell what actually happened. Officials may have throttled the iron industry unintentionally by setting prices too low to cover the costs of production. Furnaces may have ceased production in 1125 when Jurchen steppe tribesmen living in northeastern China and southern Siberia conquered northern China, but they needed iron as much as Chinese rulers did, so may have kept the furnaces alight. Crippling, short-term disaster most certainly did arrive in 1194 when the Huang (Yellow) River rose, broke its dikes, flooded vast areas, and erased the canals that had linked the iron furnaces to the imperial capital. Without canals to supply raw materials and deliver iron to users, production must have ceased, at least for a while. The canals were never wholly restored, so it is not surprising that when official figures for iron production in Henan and Hubei become available again, after the Mongol successors of Chinggis Khan (Genghis Khan) had conquered China (as the Yuan dynasty, 1279–1368), only 8,000 tons of iron per annum came from surviving furnaces, and all of it went to equip the Mongol army. Subsequently, iron smelting in Henan and Hubei ceased entirely in

1736 for reasons unknown and resumed only in the twentieth century.

At some undetermined time, Japanese sword makers developed secret skills for manufacturing blades superior to all others. Heating, reheating, and prolonged hammering created laminated steel swords, sharper and more durable than those other peoples knew how to make. The samurai warriors who used them became a privileged class. Such weapons took a long time to make and each was precious and unique, so Japanese swords did not do much to benefit the nation as a whole.

Iron in Europe

If the astounding expansion of iron production in China between 998 and 1078 had been sustained that country would have enjoyed a far more abundant supply of iron than anywhere else, and it is tempting to suppose that something like the Industrial Revolution of eighteenth-century Britain might have ensued. As things were, China remained more populous and more skilled at making silk, porcelain, and many other items than the rest of the world, but allowed Europeans—especially the British—to take the lead in expanding the scale of iron production, beginning about 1300 when larger furnaces of improved design began to attain higher temperatures in western Europe.

Brass and bronze were the preferred metals for heavy guns when they were new, because iron was liable to split under the pressure of exploding gunpowder. This was due to various trace chemicals found in most iron ores. But, by chance, iron ore from Sussex, England, lacked contaminating chemicals and in 1543, gun makers imported from mainland Europe discovered they could cast reliable iron cannon from Sussex iron. This allowed English ironmasters to produce much cheaper big guns and expand the scale of production beyond earlier limits. English ships armed with iron guns defeated the Spanish Armada in 1588, and the Royal Navy, needing heavy iron anchors as well as hundreds of cannon, became the principal market for English iron for the next two centuries.

Deforestation of the more densely settled regions of western Europe limited the supply of charcoal more

and more severely after 1300. That set a ceiling on ironworking and drove Dutch and other entrepreneurs in the seventeenth century to build furnaces in Sweden and even in the Ural mountains of Russia, where there was iron ore and forests were abundant. In 1709, however, Abraham Darby, an English ironmaster, discovered how to smelt iron by using coke (made by heating coal to drive off noxious chemicals). Since English coalfields were extensive and coal mining had already become an important industry, it then became possible to expand iron production far beyond earlier limits.

The Industrial Revolution

Possibilities widened after 1712 when Thomas Newcomen built the first steam engine, which was made of iron. It was designed to pump water from coalmines, thus enabling more coal to be mined from greater depths. James Watt's improved and more versatile steam engine (1776), iron bridges, and the first iron locomotive (built in 1802), presaged a far more massive upsurge in demand for iron to construct steamships (beginning in 1807), railroads (after 1825), and ironclad vessels (from the 1840s).

The consequent rapid expansion of iron manufacturing played a central role in what is commonly called the British Industrial Revolution. As before, civilian inventions were matched and at other times provoked by naval and army officers who sought new

and more powerful weaponry to assure military security or crushing superiority over rivals.

Wars regularly stimulated iron and steel production by expanding demand for cannon, armored ships, and other big-ticket items, and when peace cancelled wartime demands, ironmasters desperately sought new civilian markets to absorb their surplus. England's wars with France (1756–1763, 1778–1783, and 1793–1815) therefore had much to do with hurrying the Industrial Revolution along. The expansion of British iron production, in turn, facilitated Great Britain's military and economic successes.

Civilian-military linkages remained influential throughout the nineteenth and twentieth centuries, not just in Great Britain but in France, Germany, and every other country where new mines, factories, and foundries arose to match those of Britain—and whenever new wars created sudden surges in governmental purchases of armaments. Everywhere, supplies of coal and iron were essential for industrial modernization. In Germany (united after 1870) and the United States, coal- and iron-based industries expanded more rapidly than elsewhere; both surpassed Great Britain in total output well before 1900.

Technical advances came thick and fast. During the nineteenth century, chemists developed ways to detect, and either remove or increase, trace elements that affected the qualities of iron and steel. In 1856, Henry Bessemer devised a furnace that sent a blast of hot air through molten iron, turning it into steel. That

harder and stronger material became far cheaper to produce in much larger quantities than before. Thereafter, steel and specialized steel alloys displaced iron for many purposes. After lengthy experimentation, Alfred Krupp in Germany manufactured the first steel cannon, and the Prussian army showed its superiority in the field when invading France (1870–1871). That made steel preeminent for the manufacture of big guns and armored warships. World Wars I and II added steel tanks for use on land. Steel shells remain standard today.

In the twentieth century, coal, iron, and steel lost some of their former preeminence. Oil displaced coal for many purposes; aluminum and plastics displaced iron and steel less generally—but significantly, for example, in manufacturing airplanes. In the foreseeable future, steel, with its many different alloys, and iron, in its various forms, seem sure to remain the most common material humans employ for making the innumerable metallic objects we use in everyday living, as well as for building the industrial and military machinery we rely on.

Isabella I

(1451–1504)
QUEEN OF SPAIN

The marriage in 1469 of Isabella of Castile and Ferdinand II of Aragon led to the dynastic unification of Spain's two largest kingdoms. Isabella, the only reigning queen in the first century of the Renaissance, was the sponsor of Columbus's voyages to the New World. She enacted programs to restore and solidify the predominance of the Roman Catholic Church in the Iberian Peninsula.

The Iberian monarch Queen Isabella (Isabel in Spanish) I of Castile, also known as Isabella the Catholic, completed the reconquest of the Iberian Peninsula along with her husband, Ferdinand (Fernando in Spanish) II of Aragon (1452–1516). Royal sponsor of the New World voyages made by Christopher Columbus, she was the daughter of John II of Castile and Isabella of Portugal.

Isabella was named Queen of Castile after the death of her brother Alfonso in 1468, although not without incident. As a result of Isabella's marriage (1469) to Ferdinand II of Aragon—later Ferdinand V of Castile—Isabella's half-brother Henry IV promptly chose to disinherit her and appoint as the new heir apparent his own daughter, Juana. Upon the death of Henry IV (1474) Isabella appointed herself as the rightful Queen of Castile in the city of Segovia, causing a bitterly fought civil war and international conflict to erupt between the faction supporting Isabella and the faction supporting Juana (1475–1479). The Concordat of Segovia (1475) set forth the rules and regulations governing the individual participation of Isabella and Ferdinand in the governing of Castile, and the subsequent Treaty of Alcaçovas (1479) put an end to the civil war. From this point forward, Isabella

and Ferdinand ruled as equal Catholic Kings, a title conferred upon them by the Spanish-born Pope, Alexander VI, a member of the influential Borgia family.

The marriage of Isabella and Ferdinand II created a union that eventually led to the dynastic unification of Spain's two largest kingdoms, Castile and Aragon. Contrary to popular belief, neither the Catholic Queen Isabella I nor the Catholic King Ferdinand V wished to be known as monarchs of a unified Spanish kingdom. Instead, they preferred to be known in the traditional fashion as "King and Queen of Castile and León, Aragon, and Sicily, Toledo, Valencia, Galicia, Mallorca, Seville, Sardinia, Corsica, Murcia, Jaen, Algarve, Algeciras, Gibraltar, Count and Countess of Barcelona, Lords of Viscaya and Molina, Dukes of Athens and Neopatria, Counts of Roussillon and Cerdagne."

After the death of the sons of Isabella and Ferdinand, their daughter Juana became the heir and future Queen of the Crown of Castile. With her husband, Philip of Austria, Juana would give birth to the future Emperor Charles V of the Holy Roman Empire, or Charles I of Spain. Another of Isabella's daughters, Catherine, married Henry VIII of England. The inability of Henry VIII to obtain a divorce from Catherine of Aragon would trigger the break of England from the Roman Catholic Church.

Isabella's historical significance lay not only in the fact that she was the only reigning queen in the first century of the Renaissance, but also in the sweeping programs she pursued in her mission to restore and solidify the predominance of the Roman Catholic Church in the Iberian Peninsula. Notorious among these programs were the establishment of the Spanish Inquisition, the expulsion of the Jews from all Spanish

The wedding portrait of Isabella I, Queen of Castile, and Ferdinand II of Aragon, circa 1469.

kingdoms, the reform of the Spanish Church and of the religious orders, the wars against the Muslims of North Africa, and the eventual Conquest of Granada (1492), the last Muslim enclave on the Iberian Peninsula. Isabella also supported the conquest of the Canary Islands and the New World endeavors of Christopher Columbus, through which Spain would gain a new overseas empire.

The Treaty of Tordesillas (1494) was perhaps the most important international arbitration treaty signed during Queen Isabella's reign. Drawn up to ease confusion between Spain and Portugal with regard to the right of possession of New World territories, it basically divided all newly discovered lands between the two countries. Upon the death of Queen Isabella I, the Catholic, she was laid to rest in the Royal Chapel adjacent to the Cathedral of Granada, as was her dying wish. She lies entombed alongside her husband,

King Ferdinand, the Catholic, and their daughter Juana and her husband, Philip.

Isabella's reign gave birth to a Renaissance decorative and architectural style known as Isabellaine. Along with her desire to bring the Catholic faith to an ever greater number of people, Isabella also empowered one of the most crucial tools of empire and civilization—the first grammar of a European language, compiled by the Spanish humanist Elio Antonio de Nebrija.

Islam is both a worldwide community of believers and a major world belief system based on submission to one God, Allah. In the twenty-first century there are almost a billion and a half Muslims (people who accept Islam as their faith) in more than two hundred countries.

Although Islam was initially historically identified with Arabs, today only around 15 percent of the world's Muslims (the people who accept Islam as their faith) are Arabs, with the largest national communities of Muslims being in southern and southeastern Asia. The historic Islamic community began in the seventh century CE in the western part of the Arabian Peninsula; within two centuries the Muslim world stretched from Central Asia to northern Africa and Spain. The term *Islam* refers to a worldwide community of believers and to one of the major belief systems in the world.

The core of the belief system of Islam is the affirmation that one God (Allah) exists. The word *Allah* means in Arabic “the divinity.” The word *islam* means “submission,” and the belief system is based on submission to the one God, with the person engaging in submission being called a “Muslim.” Muslims understand their faith to be a continuation of the message of God presented to humanity through a series of messengers and prophets, including Abraham and Jesus. In the Islamic belief system the final presentation of the message of God was made through the Prophet Muhammad, who lived in Mecca and then Medina in modern Saudi Arabia at the beginning of the seventh century CE. The revelation was recorded and preserved in the Qur'an, the holy book of Islamic faith.

The basic requirements of the Islamic belief system are frequently called the Five Pillars of Islam. The first pillar (*shihadah*) is bearing witness publicly to the belief that “There is no divinity but Allah and Muhammad is the messenger of Allah.” Praying (*salat*) is the second pillar. Praying involves performing five prescribed prayers daily. The third pillar (*zakat*) is taking the responsibility to contribute alms to provide assistance to the poor in the community. Undertaking the fast during the month of Ramadan is the fourth pillar. The fifth pillar is performing the pilgrimage (hajj) to Mecca at least one time during the believer's lifetime, if possible. Each of the pillars is a responsibility for the individual believer, and no priesthood or clergy is required to fulfill any obligation. Although “striving in the path of God” (jihad) is an expected part of the life of faith for Muslims, jihad defined as “holy war” is not one of the Five Pillars of Islam.

The Formation of Community and Faith

Muhammad was born in Mecca around 570 CE. He was part of an active merchant community that was involved in trade between the Indian Ocean and the Mediterranean Sea. In addition to being a commercial center, Mecca was a religious center with a shrine that housed important religious relics from many of the tribes in the region. Muhammad's own family was influential in both religious and commercial activities, but his father died before he was born, and his mother died when he was still young. As a young man he gained a reputation for reliability

and married a prosperous widow, Khadijah, whose affairs he managed. His life was transformed when he experienced his first revelations around 610 CE.

The Meccan belief system at that time was basically polytheistic, but Meccans were familiar with Christianity and Judaism. Muhammad preached a message of strict monotheism and soon aroused the opposition of the Meccan merchant elite. After many struggles he and his small community of followers moved to Yathrib, a neighboring oasis community whose leaders invited Muhammad to come and be the arbitrator and judge in its disputes. The oasis became known as Medina, or “the city [Medina] of the Prophet.” This migration in 622 CE is called the Hijra and marks the beginning of the Islamic community as a distinct entity. Muslims date the years of the Islamic era from the Hijra, with 622 CE being year 1 in the Islamic calendar. This calendar is based on a lunar year of approximately 354 days or twelve lunar months.

During the next ten years most of the people in the Arabian Peninsula became Muslims or were allied in some way with the new Islamic community. The defeat and conversion of Mecca was an important step in this process. The shrine of the Kaaba, a cube-shaped structure at the center of Mecca, was purified of polytheistic relics and recognized as the altar of Abraham. In the prescribed prayers Muslims were to face the Kaaba (for a short time they faced Jerusalem), and the building became the center of pilgrimage rites. The basic foundations of the Islamic belief system and the Islamic community were laid.

The Era of the Caliphs

The Islamic community was dynamic by the time of Muhammad’s death in 632 CE. Some confusion existed about the transition to a community without Muhammad. The majority of the community accepted the idea that the successor (*khalifah* or caliph) to Muhammad as leader would be one of his close companions, Abu Bakr. A minority within the community came to believe that the idea was an error and argued that the first successor should

have been the son-in-law and cousin of Muhammad, Ali. In later tradition this minority group came to be identified as the faction (Shiah) of Ali (Shi’as), whereas the majority were called “Sunni” (those who follow the Sunnah or precedents of the community).

The first four caliphs were all close associates of Muhammad (two were the fathers of wives he married after Khadijah died), and their rule is identified by Sunni Muslims as the era of “the Rightly-Guided Caliphs” (632–661 CE). Under their leadership Islamic armies conquered all of the Sasanid Empire and most of the Middle Eastern territories of the Byzantine Empire. Through these conquests the Islamic community became the heir of the great imperial traditions of Persia and Rome as well as the Middle Eastern monotheistic traditions. In structure and administrative practices the emerging caliphate resembled the older empires that had been conquered.

The political history of the Islamic community during the early centuries involves the rise and fall of dynasties controlling the caliphal state, and the political experiences of the community shaped the belief systems that developed. Civil war brought an end to the era of the Rightly-Guided Caliphs, and the new political community was ruled by the Umayyad dynasty (661–750 CE) and then by the Abbasid dynasty (749/750–1258).

Early Abbasid caliphs built a new capital at Baghdad, not far from the location of ancient imperial capitals. Although the Abbasid state was strong, it never established control over all of the territories of the Islamic world. Umayyad princes continued to rule in the Iberian Peninsula, and gradually independent Islamic states were established across North Africa. By the end of the tenth century CE three caliphs claimed authority in parts of the Islamic world—an Umayyad ruler in Spain, a Shi’i ruler in Egypt, and the Abbasid caliph in Baghdad. Local military rulers, who came to take the title of “sultan,” increasingly dominated political affairs. The Mongol conquest of Baghdad in 1258 CE brought an end to the Abbasid caliphate. Although the concept of the caliphate as a symbol of Islamic unity continued, basic Islamic

A mosque in Mecca in the early twentieth century.

political organization took the form of sultanates, representing rule by military commanders. This transformation was possible because of the evolution of the nature of the Islamic community itself.

The Faith-Based Community

During the early centuries of Islamic history the caliphate was the most visible aspect of the new Islamic community. However, the development of the Islamic belief system provided the basis for a faith-based community that involved more than an allegiance to a particular ruler or political system. The definition of a legal and normative framework that shaped politics but that was independent of the state helped to create a sense of community identity. The development of popular devotional organizations associated with the growing importance of Sufi (Islamic mystic) brotherhoods strengthened this identity.

The Islamic belief system initially developed within the framework of the caliphate but was not tied to the specifics of the political system. Scholars, not political leaders, undertook the important functions of interpreting the Qur'an and organizing the traditions (hadith) of Muhammad as basic sources for law and guidance. These scholars, literally the "learned people" (*ulama*), never became an ordained clergy and maintained independence from rulers. However, the political and legal dimensions of the Islamic faith were an important part of the belief system. These dimensions were the primary area of disagreement among Sunnis and Shi'as. The Sunnis

believed that the historic caliphate was Islamically legitimate, whereas the Shi'as insisted that the only legitimate ruler would be the divinely designated imam (an Islamic leader) who would be a descendant of Muhammad. Most Shi'as are called "Ithna Ashari" or "Twelvers" because they believe that the twelfth imam in the series was taken into divine seclusion and will return at some future time to establish God's rule.

The *ulama* during Abbasid times developed a framework of legal concepts and precedents that provides the foundation for the legal and normative structures of the sharia (Islamic law). No single system of canon law developed. Instead, among the Sunni majority, four schools of legal thought, each identified with a major early scholar—Hanafi (Abu Hanifa, d. 767), Maliki (Malik ibn Anas, d. 796), Shafi'i (Muhammad Shafi'i, d. 819), and Hanbali (Ahmad ibn Hanbal, d. 855)—were accepted as authoritative. Among the Shi'as most recognized the legal thought of Jafar al-Sadiq (d. 765), the sixth imam. In these schools the fundamental sources of the sharia were agreed to be the Qur'an and the traditions or Sunnah of Muhammad. Although theology was important, the core intellectual disciplines for Muslims became legal analysis (*fiqh*) and collection and analysis of the hadith (reports of the words and actions of Muhammad). Differences arose regarding analogical reasoning and consensus of the community. Use of independent informed judgment in analysis was called *ijtihad*. In later centuries Sunnis limited its scope more than did Shi'as.

The content of this legal structure emphasized the universality of law based on God's revelation and the equality of all believers. It was not strictly speaking a code of law; it was rather a framework for a just and virtuous society. The sharia defined both the duties to God and social responsibilities. It covered commercial practices, family life, and criminal behavior. This vision of society did not depend upon a particular state structure and could be presented by scholars rather than rulers and soldiers.

The faith of the majority of the population was also shaped by popular preachers and teachers whose devotional life was an inspiration. The development of special devotional paths or *tariqahs* is associated with what came to be called "Sufism," the mystical piety of early inspirational teachers. By the eleventh and twelfth centuries CE social organizations associated with these devotional paths became an increasingly important part of Islamic societies. The devotional paths emerged as brotherhood organizations that were instrumental in the Islamization of societies in central and southeastern Asia and sub-Saharan Africa.

Expanding Community and the Great Sultans

The Islamic world virtually doubled in size between the tenth and the eighteenth centuries. Great trade networks brought Islamic merchants to most regions of the Eastern Hemisphere. Islamic scholars and Sufi teachers followed, and dynamically growing communities of believers developed as interactions with local people set in motion activities that resulted in the gradual Islamization of societies.

By the sixteenth century the great central states of the Islamic world represented a commanding dynamism. In the eastern Mediterranean the Ottoman Empire began during the thirteenth century in the Aegean area, conquered Constantinople (modern Istanbul, Turkey) in 1453, and, by the eighteenth century, controlled much of the Balkan Peninsula, the Arab world, and North Africa. In southern Asia the smaller Islamic sultanates of medieval times were replaced

by the Mughal Empire, which dominated virtually the entire Indian subcontinent by the seventeenth century. In western Africa a series of increasingly Islamized states beginning with medieval Ghana and Mali and ending during the sixteenth century with the Songhai Empire established Islam as a major historic force in the region. Similar developments took place in southeastern and Central Asia.

A dramatic change occurred in the Persian-Iranian heartland. Iran had long been an important part of the Sunni world, with some Shi'a minority groups. However, around 1500 a militant popular religious group called the "Safavids" conquered much of modern-day Iran and beyond. During the next century the Safavid rulers declared Ithna Ashari Shi'ism to be the religion of the state, and most Iranians converted. Shi'i scholars came to the Safavid Empire, especially from the Arab world, and received privileges that gave the *ulama* in Shi'i Iran a special influence that has continued to the present.

Challenges of the Modern Era

This powerful and expanding Islamic world had long interacted with western European and Christian-majority societies. These interactions entered a major new phase during the eighteenth century with the transformation of western European societies, especially through the Industrial Revolution, and the beginnings of European imperialist expansion. Throughout the Islamic world Europeans came to dominate Islamic lands, and Muslims responded in many ways. Muslims mounted major efforts to fight European expansion, as in the wars led by the emir (ruler) Abd al-Qadir in Algeria after the French invasion of 1830. Most military opposition failed.

Leaders in major Islamic countries introduced programs of reform to reshape their societies and states using Western models. Early reformers included Muhammad Ali in Egypt (reigned 1805–1849) and the Ottoman sultan Mahmud II (reigned 1808–1839), whose programs laid the foundations for the emergence of modern-style secular states. Later other reformers

A leaflet in Arabic and Chinese used by Muslims in China in the nineteenth century.

emphasized intellectual and religious dimensions. By the end of the nineteenth century efforts to create an effective synthesis of Islam and modernity resulted in the movement of Islamic modernism. Major figures are Muhammad Abduh (1849–1905) and Jamal al-Din al-Afghani (1839–1897), whose ideas influenced groups as diverse as the Muhammadiyya movement established in Java in 1912 and intellectuals in India and North Africa. A different emphasis in reform is provided by more puritanical movements that seek a “return” to a more strict adherence to Islamic norms interpreted in a relatively literalist manner. This mode of reform has deep roots in Islamic history and can be seen in the premodern movement of Muhammad ibn Abd al-Wahhab (1703–1792), whose ideas have been an important part of modern Islamic revivalist movements.

The broad spectrum of responses to the challenges of modernity in the nineteenth century extended from the Westernizing programs of state reform to the explicitly Islamic modernists and fundamentalists. The work of all of these people set the framework for the developments of states and societies in the Muslim world during the twentieth century. By the end of the nineteenth century few groups could be considered purely non-modern (or, in the terminology of twentieth-century social scientists, “traditional”), since even the most conservative were interacting with the modernity of the time. That era was still largely defined by Western European experiences, so that modernization tended to be viewed as a process of Europeanization or Westernization. But by the end of the nineteenth century, distinctive non-European modes of modernity were beginning to be visible, and the emergence of these different styles of modernity would play an important role in shaping the history of Muslim societies and thought in the twentieth century.

Twentieth-Century Modernity

Global Muslim communities experienced important transformations during the twentieth century. At the beginning of the century, most of the Muslim world was under direct or indirect European imperialist control, and the emerging political systems were primarily conceived as Western-style nation states. Explicitly Islamic movements and organizations were often viewed, even by “modern” Muslims, as anachronisms and obstacles to modernization. By the end of the twentieth century, however, virtually every Muslim majority society was politically independent, and classical European imperialism was an image from a seemingly distant past. An explicitly Islamic republic was created by a revolution that overthrew a Westernizing autocracy in Iran in 1979, and the new Islamic republic was sufficiently strong at the beginning of the twenty-first century to be viewed as a potential nuclear power and as an important major regional power. Muslims and Islamic movements became major influential agents in global affairs.

Prayer carries us half way to God, fasting brings us to the door of His palace, and almsgiving procures us admission. • Qur'an

This transformation involved three broad historical phases, which can be defined in terms of the evolution of modernity itself during the twentieth century. In the era of domination by European imperial powers during the first half of the century, most new movements followed European-style patterns of political development. Resistance to European rule took the form of nationalist movements, and social and political reforms were generally secular in orientation. Modernity was defined in Western European terms. The most successful of these movements was led by Mustafa Kemal Atatürk, who built a secular nationalist state in Turkey after the collapse of the Ottoman Empire in World War I.

In the middle of the century, following World War II, the second phase was shaped by the experience of newly-achieved political independence. Most Muslim states became politically independent, and various forms of secular and radical nationalism dominated the intellectual and political scene. Leaders such as Gamal Abd al-Nasir in Egypt and Ben Bella in Algeria incorporated Islamic themes into their radical nationalist programs, but these programs were not primarily Islamic in orientation or identification. By the 1960s, it appeared that the most important political developments and reform movements in the Muslim world represented radical programs of modernity that competed with older visions of modernity. Competing definitions of modernity—or multiple modernities—shaped Muslim policies and visions. An important culmination of this development was the Islamic Revolution in Iran in 1979, when radicalism was defined in explicitly Islamic terms, and the older more secular forms of radicalism became marginalized.

By the final quarter of the twentieth century, distinctively Islamic modernities were articulated as the bases for social visions and political programs. The new movements in the third era of twentieth-century Muslim history had some roots in earlier organizations that were modern in organization but more puritanical in terms of intellectual content. The most important of these groups are the Muslim Brotherhood, established in Egypt by Hasan al-Banna in

1928, and the Jamaat-i Islam, established in 1941 in India by Abu al-Ala Mawdudi.

In the final decades of the century, the major signal that the radical and the secularist nationalist movements had failed to bring the expected prosperity and freedom to Islamic peoples was the Iranian Revolution of 1979, which brought to power a regime dedicated to a full implementation of Islamic rules and norms. During the early 1980s many other movements with strongly defined Islamic goals and agendas came to prominence. These movements represent the emergence of what came to be called “political Islam” because the primary focus of the programs was the control of the state. Some movements, such as the Islamic Salvation Front in Algeria, contested elections, whereas others, such as the Mujahidin in Soviet-occupied Afghanistan, engaged in violent opposition defined in its terms as jihad. These movements of jihad became a significant part of the Islamic experience of the 1990s. In the context of globalization, militant global networks such as al-Qaeda represented an important part of Islamic interaction with the world. However, such movements remained only a small part of Islamic life and often were in conflict with the mainstream Islamic organizations and sentiments that reflected the views of the majority of Muslims.

Although the movements of political Islam attracted the most attention, other important trends also developed during the 1980s. Intellectuals gave increasing attention to the definition of the place of women in Islamic society, and by the beginning of the twenty-first century, an “Islamic feminism” had emerged. This feminism involved a reexamination of the Qur'an, noting the Qur'an's emphasis on the equality of all believers and then noting the influence of more patriarchal perspectives in the way that the Islamic tradition was historically defined. Similarly, some intellectuals have emphasized pluralistic dimensions of the Islamic worldview and tradition and have also drawn back from the emphasis on political activism as a means for imposing Islamic norms.

Some of the impetus for these developments has come from the emergence of minority Islamic communities in western Europe and North America as important parts of the broader Islamic world. In those regions issues of gender equality and religious pluralism have great importance for Islamic community life.

New Twenty-First Century Realities

The continuing significance of religion at the beginning of the twenty-first century confirms the development of forms of modernities that are different from the definitions of modernity popular during the nineteenth and much of the twentieth century. Contrary to the expectations of theories of modernization in those periods, modernization did not mean the inevitable nonreligious secularization of state and society. In the Muslim world, new movements develop that are not simply continuations of old-style movements from premodern times or even twentieth century modern movements in some slightly different form.

The new movements that get the most attention are the militant movements like al-Qaeda. These are clearly different from the early Sufi movements of resistance to European imperialist expansion in the nineteenth century, and from the activist radical nationalist movements of the twentieth century. Globalization and the new electronic media of communication transform the nature of organization and shape the way that the messages of the movements are framed.

The largest of the new movements are not, however, the terrorist organizations. Throughout the Muslim world, new popular preachers and teachers have millions of followers in many countries. Islamic television ministries like that built by the Egyptian Amr Khaled are reshaping the ways that many Muslims participate in the sense of belonging to a global community of believers. Analysts speak of “iMuslims” and “e-jihad” in ways that illustrate the new modernities of Muslims in the world of the twenty-first century. The

long history of the flexible adaptations of the Islamic community and belief system to changing historic conditions suggests that new forms of Islamic institutions and perspectives will continue to be defined by believers.

Islamic Law

The authority of the Qur'an, as well as the development of schools that interpreted and codified the Prophet Muhammad's (c. 570–632 CE) traditions, shaped Islamic law (*sharia*) over many centuries. The *sharia* extends beyond a legal framework to instruct Muslims about personal, religious, social, and political aspects of life.

The word *sharia* is normally translated as Islamic law, but not law in a narrow sense. It might better be translated as “a way of life,” as is suggested by its literal translation, “a way” or “a path.” In other words, the *sharia* instructs about all that is personal, religious, economic, social, and political. Generally, only four sources for the prescriptions and prohibitions of the *sharia* are recognized: the Qur'an, the Sunna, consensus, and analogy. But this is an idealization of how the law came to be formed, as it actually took several centuries, the growth of the schools (*madrasahs*), and codification of the traditions (*hadith*) of Muhammad and his companions for the *sharia* to reach full development.

The first source of law for the *sharia* is the Qur'an. For Muslims all aspects of life fall under the purview of the commands of God, for he is the almighty and supreme lawgiver. His will is recorded in the Qur'an, and so following it is a religious duty of a Muslim. The Qur'an is thus both scripture and legal document.

The Qur'an repeatedly orders Muslims to obey Muhammad and states that he is their example. As the Prophet, his functions included explaining and applying the revelations, and acting as the judge for his people. And, since Muhammad was divinely guided, his actions and sayings are God's will. Thus, the conduct of Muhammad, known as the Sunna and

transmitted in the form of *hadiths* (traditions), is also legally binding. In the Sunna, many of the legal subjects of the Qur'an are elaborated and many others are addressed. Thus, while the Qur'an is the supreme source of the *sharia*, many of its laws are derived from and dependent upon the interpretations of the Sunna. There is a considerable range of opinion about the Sunna, even today. For many Muslims the traditions serve only as a general guide; but for just as many, they serve as a source of law second only to the Qur'an.

There is a *hadith* that states Muhammad said, “My community will never agree in error.” If *hadiths* are indeed legally binding, then this *hadith* implies that consensus is an acceptable source of law as well. Thus, whatever is accepted by the entire community as true or prescribed must be treated as true or prescribed.

The fourth source of law is reason by analogy. For example, if the Qur'an prohibits the use of wine, then narcotics are also, by analogy, prohibited. The principle is that the impairment to one's judgment caused by wine is analogous to that caused by narcotics. If the former is prohibited, then the latter is also.

The Major Schools of Law

That Muslims came to see these four sources as the only legitimate ones is largely due to the work and influence of the great jurist, Abu 'Abd Allah ash-Shafi'i (767–820 CE). Prior to him, Muslim rulers had laws in their empires; however, these laws could vary enormously from region to region. Arab tribal law, Qur'anic prescriptions, and local Byzantine or Sasanian law were used as needed. A rapidly expanding empire and administration forced them

to be expedient. In the cities of the empire various law schools were forming. Each of them used slightly different methods and so produced different laws. In Medina a school formed around Malik ibn Anas (c. 715–795 CE), who produced the first Muslim legal compendium, in which he discussed various legal issues by citing the relevant verses from the Qur'an and hadiths from the Sunna, and then interpreted them in light of consensus of opinion of jurists in Medina. Another important school was formed around the scholar Abu Hanifah (699–767 CE) in Al-Kufa. The cosmopolitan nature of the city and its distance from the Mecca and Medina resulted in many different interpretations of the law. For example, in the case of a wrongful death in Medina, the guilty person's whole tribe was responsible for his actions and had to pay compensation to the family of the dead man. In Medina, Arab tribal ways were still the custom. In Al-Kufa, the Arab tribal system was weakening and being replaced by new urban social structures. Thus, only the guilty party was responsible for paying the compensation. The Hanafi school in Al-Kufa respected the Qur'an and Sunna, but was more open to outside influences such as Roman law and the use of reason.

Ash-Shafi'i, seeing these differences, thought that the methods used to produce Islamic laws should be the same from place to place and ruler to ruler because the sharia, as God's law, must itself be uniform. The supremacy of the four sources and yet another school of law, the Shafi'i, developed out of his work. So influential was ash-Shafi'i and his emphasis on the Sunna that both the Maliki and Hanafi schools eventually largely adopted his four-sources model for themselves.

The last of the four schools of law that have survived until today in Sunni Islam is that of Ahmad ibn Hanbal (780–855 CE). Ash-Shafi'i, despite his focus on the Qur'an and the Sunna as sources of law, represents a compromise between those who used reason as a source and those who rejected it. Ibn Hanbal belonged to this latter group. Each and every law must be rooted in either the Qur'an or the Sunna. Ibn Hanbal took this principle so seriously that it is said

that he refused to eat watermelon because it was not mentioned in the Qur'an, nor did he know of a tradition from the Sunna that indicated that Muhammad had eaten it. (This is hardly surprising, since watermelon would not have grown in any of the regions in which Muhammad had lived.)

There were several other schools of law in Sunni Islam, but only the Maliki, Hanafi, Shafi'i, and Hanbali survive. The Abbasid dynasty adopted the Hanafi school. It spread to India and from there to east Africa and Southeast Asia. The Ottomans also adopted it and so today it is the law followed by Muslims of Bosnia and Herzegovina, Turkey, Syria, Iraq, Jordan, and portions of Egypt and North Africa. The Maliki school spread west from his home in Medina to Africa. The Sudan, Eritrea, Somalia, Libya, Tunisia, Algeria, and parts of Egypt and Nigeria practice Maliki law. The Shafi'i school spread in opposite direction. It began in Egypt but moved to South Arabia, then east along trade routes to the Indian coast and Southeast Asia. Most Muslims of Malaysia, Singapore, Indonesia, the Philippines, and Sri Lanka adhere to the Shafi'i school. The last school to form, the Hanbali, is only practiced in Saudi Arabia.

Islamic law in Shi'a tradition is different. The Qur'an and the Sunna are still the most important sources of law. However, Sunnis and Shi'as differ on other sources of law in several significant ways. First, the traditions that form the Sunna for Shi'i Muslims are different than those for Sunni Muslims. Second, the legal opinions of the imams are also binding for Shi'as because God guided the imams. And third, for Imami (or Twelver) Shi'i Muslims (whose imam is hidden) consensus has no legal force, but the use of reason by the top jurists, who are thought to be under the influence of the hidden imam, is encouraged. Today, this school of law continues to be practiced in Iran.

The Use of Reason

Each of the different law schools had a different approach to the use of reason. For some, the use of reason in matters of law was not much different than

the scholar's opinion. But this approach was eventually rejected by almost all and the common view was that a jurist had no right to produce law on the basis of what he supposed to be right. Instead, opinion had to be backed by a source such as the Qur'an or the Sunna. The problem was that if each jurist used his own opinion, the law would not only vary from region to region, but from person to person. And, more importantly, law based on human opinion was not divine law. This use of opinion was strongly opposed by the Shafi'i and Hanbali schools. However, in the early Maliki and Hanafi schools opinion in the form of reason was used, although many of their conclusions were later supported by use of the four sources of Islamic law.

Opinion or judgment was still used in analogy and consensus. That is, the jurist had to determine what was common between a previous case and a new case when an analogy was adduced. (In the example above, it was the impairment caused by both wine and narcotics.) Likewise, consensus as a source of law implies consensus of opinion. However, because of the diversity of Muslims, the use of this method was impractical in all but the most basic beliefs and practices. In addition, the opinions, or more accurately the formal legal judgments, of Muhammad's companions, such as the rightly guided caliphs, were often considered legally binding.

Further Options for the Jurist

There are two other sources of law that are closely related to each other and to the use of reason. The first allows judges some leeway in the interest of fairness. The jurist is allowed to pick the solution that seems to him the fairest of all possible solutions to a legal case. The second is consideration of public welfare. That is, a regulation that prevents harm to or secures a benefit for the community can be issued by a jurist.

Each of these rational methods is practiced by at least some of the schools of law. None, including the use of analogy, is allowed to infringe on stipulations provided by the Qur'an and the Sunna. Nor do these methods have relevance when it comes to religious

doctrines and practices; such matters are the exclusive jurisdiction of the Qur'an and the Sunna. However, they do demonstrate that the sharia can be and has been partially adaptable to new situations as they arise, despite the rigid framework that ash-Shafi'i promulgated.

Customary Law

Prior to the revelations to Muhammad, the Arab tribes may not have had a formal legal system, but they did have traditional ways of doing things that, even if they were not written down, did regulate and guide their lives. This Arab tribal custom survived the coming of Islam. In fact, Arab tribal law and perhaps even some of Roman (Byzantine) and Sasanian law as practiced in Egypt, Syria, and Iraq were incorporated into the sharia.

In the sharia, custom is not normally a formal source of law, and when it is, it is not given much prominence. In practice however, it had an enormous impact. Custom was absorbed into the sharia in many ways. Sunna not only consists of that which Muhammad said and did, but also that of which he tacitly approved. That is to say, activities of Muslims of Muhammad's time, if he did not explicitly comment on them, are assumed to have had his silent approval. The Maliki school based in Medina held that as the ones living in the home of the Prophet, they, more than anyone else, practiced the customs of which Muhammad approved. For the founder of the Maliki school, Malik ibn Anas, the local custom of Medina was equated with consensus—since all (Medinan) Muslims agreed on their custom. In this manner more Arab tribal custom entered the sharia.

Qanun (Sultanic Prerogative)

The sharia is normally thought of as encompassing all aspects of life. It provides regulations concerning activities as diverse as performing prayer, paying tithes, getting married, committing adultery, charging interest on loans, receiving inheritance, obeying authorities, and taxing Jews and Christians. The

religious, social, economic, and political all fall under the purview of the sharia. And so it is assumed that the sharia regulates all aspects of life. However, the rulers of Muslim territories—caliphs, governors, and later sultans—found that they needed to make their own regulations for activities not addressed by the sharia. These regulations, civil laws, or codes came to be known as *Qanun*, from a Greek word for imperial taxes.

Qanun (especially in the sense of financial regulations issued by the ruler) began quite early in the Islamic world with the second caliph, ‘Umar I (c. 586–644 CE). He decided that the newly conquered land in Iraq that had belonged to the Sasanian state, aristocracy, and priesthood should not be divided among the conquerors, but held for the payment of salaries of Muslims. Likewise, the land tax system ‘Umar adopted was based on the Sasanian model. For such practices the sharia is silent, and so there is no conflict between it and *Qanun*.

From *Qanun* as financial regulations, which were issued by the caliph or some other ruler, developed the practice of sultans issuing laws not found in the sharia, which they ordered without any consideration for the legal principles that were used to establish laws in the sharia. That they could do so was based on power—their authority as the ruler.

Despite these dictatorial actions by some sultans, the *Qanun* and the sharia have generally been free of conflict. Originally, *Qanun* did not trespass into areas where the sharia had jurisdiction. Additionally, in the early years of Islam, there was more allowance for other sources of laws for the sharia. For example, decrees, like those by ‘Umar, along with customary law, could be integrated into the law by interpreting them as in accord with the behavior of Muhammad, his companions, and the early Muslim community, and not exclusively that of Muhammad. Also, a product of ash-Shafi’i’s reform was to produce a narrower definition of what constituted sharia. As a result, many of the administrative concerns of the caliphs and sultans fell conveniently outside of the sharia’s jurisdiction. This suited the sultans, who were eager to increase their own power vis-à-vis that of the caliph,

whose duty it was to enforce the sharia. Finally, the right of the sultan to make and enforce law was justified within the sharia by arguing that it served the public interest. And so jurists, and hence the sharia, gave to the sultan the jurisdiction in matters of the military, non-Muslim taxes, conquered land, penal codes, the economy, and any matter on which the sharia was silent. Moreover, the public had a religious duty to follow these orders from the sultan.

Sharia and Qanun

The situation changed somewhat after the fall of the Abbasids in 1258, when the sultan’s authority to generate all manner of laws greatly increased. The Turks and the Mongols brought from Central Asia a tradition that gave the ruler the power to issue decrees for the sake of justice and the welfare of the state as he saw fit. This form of state law became common in the Ottoman and Mughal empires. Under the Ottoman sultan Süleyman I (1494 or 1495–1566) an official set of *Qanun* were promulgated in the empire. Generally, a sultan would issue an edict as the need arose. These first applied only to administrative, financial, or penal codes. For example, under the Ottomans, guilds developed codes that judges of the *sharia* implemented. However, later in the Ottoman empire, *Qanun* also addressed property laws, a subject that is well covered by the sharia. Some jurists criticized this, as they believed that the sultans were overstepping their rights and could not supersede the *sharia* under any circumstances. Others supported the sultans by invoking legal principles of the good of the community, customary law, or even traditional laws, especially in newly conquered territories.

Traditional Laws in African and Asian Societies

Just as the pre-Islamic Arabs had customary laws, so too did the peoples to whom Islam came later. No less than those of the Arabs, the indigenous customs of these peoples, particularly in Africa, south Asia, and Southeast Asia, were very durable. However, they

could not be absorbed into the sharia through Sunna by means of tacit approval and consensus. Nor did these traditional laws, unlike Qanun, try to avoid the jurisdiction of the sharia. The traditions had to stand apart or even in opposition to the sharia. For some Muslim peoples, the social reality did not concur with the religious ideal that the sharia was the sole guide to a Muslim life. Islam became their religion, but not their way of life.

Of course, in reality there was often a compromise between the sharia and custom. At one end of the spectrum, the religious courts that implemented the sharia had largely eliminated local custom, and at the other there may not even have been religious courts, so that all legal matters fell under the purview of customary courts. However, the two could also operate in conjunction, dividing up the legal realm between them. That the sultan had some discretion in this matter made it easier to join traditional laws and the sharia. Occasionally, traditional practices could still be sanctioned by the sharia through the use of various legal means, such as juristic preference and ensuring public welfare. It was also possible for the sharia to function within the established religious courts, but for people to simply ignore the courts in favor of traditional ways. North Africa, India, and Southeast Asia are three regions of the Muslim world where people have often preferred their traditional laws and customs to the all-encompassing claims of the sharia. And, as we see below, in these contexts, an accommodation was often made between the two legal systems producing unique forms of Islamic law or at least unique ways in which it was enforced.

North Africa

In North Africa, the sharia and local custom often differed about such matters as marriage, inheritance, and rent for agricultural land. For example, when a Berber man marries, his family makes a payment to the bride's father, not to the bride as specified in the sharia. Nor, in direct contradiction to the Qur'an

and the sharia, is a woman allowed to inherit property under Berber custom. And the Berber practice of renting farmland by paying a percentage of the crops to the owner goes against the sharia's demand for a fixed, predetermined monetary fee. In matters of inheritance, some Berbers simply ignore the religious courts of the sharia in favor of custom, and in the matter of land rental, the sharia courts have come to recognize and administer the customary practice. Of course, this becomes even more complicated because the customs might differ among the Berbers of Tunisia, Morocco, and Algeria and even among those of a single country. In other regions of Africa, the sharia and local custom have combined to form a single, composite legal system.

India

In India, Muslims have always been a minority among a very large Hindu population. Hindu customs and laws therefore remained dominant even among the Indian Muslims. This is particularly true for inheritance and marriage laws. Several Muslim groups, following certain Hindu practices, excluded females from inheritance. Other Muslims, in the south, did direct inheritance to a woman and her descendants. Both practices violate the strict proportions assigned to various male and female family members by the sharia. Moreover, according to the sharia, no more than one-third of an individual's estate can assigned by him. This means that at least two-thirds of it must be divided in the stipulated proportions. Again, some Muslims followed the practice of Hindus, which allows the whole estate to be distributed as desired. With respect to the marriage, Muslim Indians of the South do exchange money, but it is the bride's family who makes a payment to the groom, a custom called dowry. Even the charging of interest on loans, an activity that is expressly forbidden in the sharia, was practiced by some Indian Muslims. Therefore, it seems that for Indian Muslims living in a Hindu society, customary practice was often more compelling than the sharia.

Southeast Asia

The third region in which the sharia and traditional ways clashed is Southeast Asia. Islam did not come to the region by conquest, so the Islamic legal system was not imposed on the native peoples of what are now Malaysia and Indonesia by force. Thus, unlike Muslims of North Africa and India, where elements of customary practice survive despite the presence of the sharia, Muslims in Southeast Asia continued to follow their traditional customs. For example, the sharia has not overridden the customs of the matrilineal societies on the island of Sumatra. In these societies, unlike in the Middle East, people trace their family ties only through their mother's family. This means that the relatives who matter most when it comes to inheritance are your mother's parents and her brothers and sisters.

The Ideal Versus the Reality

The assertion that the sharia, as God's eternal divine will for humanity, is applicable to all Muslims, at all times, in all places, and in all circumstances remains an ideal, but is often modified by the actual local practice of many Muslims. Customs concerning family and finances, particularly when combined as in issues of inheritance and marriage, tend to have a tenacious hold. Even in Arabia itself some Yemeni tribes refuse to abandon their custom of denying women the right to own property in contradiction to the sharia. Historical factors such as the manner in which Islam was

brought to a region and the degree to which people have adopted Islam affect whether it is the sharia or customary practice that is followed in daily life.

Islamic World

The Islamic (Muslim) world refers in a social or cultural sense to the community of Muslims spread across the globe. The term is also used in a geopolitical sense to refer to the collective of nations or states in which Muslims constitute a majority or in which Islam is the dominant faith, including politically. The Muslim world is also known collectively as the *ummah*.

The Islamic world is generally defined contemporaneously as consisting of nation-states whose population contains a majority of Muslims. The individual nations are not all contiguous with one another, although in particular regions, such as the Middle East, several of them are. It is a world of enormous diversity, including numerous ethnic groups, a wide variety of languages, cultural practices, and social customs. This fact appears to mirror the diversity promised in the Qur'an as part of the divine design and as a manifestation of divine mercy: "And of His signs," says the Qur'an, "is the creation of the heavens and the earth and the diversity of your tongues and colors. Surely there are signs in this for the learned!" (30:22).

The Ummah

The term "Islamic world" may be understood to be congruent with the Arabic term *ummah*, a nebulous, yet powerfully emotive concept that has existed since the advent of Islam itself. *Ummah* means "community" or "nation," and in general usage came to refer to the worldwide collectivity of Muslims, regardless of precisely where they lived.

The word *ummah* is of Qur'anic provenance and occurs sixty-two times in the Islamic scripture. In

specifically Qur'anic usage, *ummah* does not always refer exclusively to Muslims but to the righteous and godly contingent within a religious community. Thus the righteous members within the religious communities of Jews and Christians comprise "a balanced nation" (in Arabic, *ummah muqtasida*, Qur'an 5:66) and "an upright nation" (Arabic *ummah qa'ima*, Qur'an 3:113). The community of righteous Muslims is described in the Qur'an as *ummah wasat* ("a moderate or middle nation") and one that summons to the good and enjoins what is right (Qur'an 3:104). It is part of the divine plan, the Qur'an asserts, that there should be a multiplicity of religious communities, for "if He had so willed, He would have made you a single community" (Qur'an 5:48).

In the Constitution of Medina drawn up after the emigration of the Prophet Muhammad to Medina from Mecca in 622 CE, the Muslims and the Jews there are described as constituting a single community (*ummah*) with mutual rights and obligations. After the death of the Prophet in 632 CE, Islam expanded out of the Arabian Peninsula into the rest of western Asia and beyond. By the third century of Islam (ninth century of the common era), the Islamic realm stretched from the Indus River in southern Asia to the Oxus in Central Asia to Andalusia in southern Europe. In common—meaning extra-Qur'anic usage—the term *ummah* progressively came to refer exclusively to Muslims residing in far-flung lands united by their faith into one transnational and transregional community, or a diaspora.

As far as *ummah* may be regarded as having a political dimension, some political theorists of the medieval period conceived of this transregional Muslim polity in the following way. Theoretically and ideally speaking, the *ummah* would be united under the rule of one

Jean-Léon Gérôme, *La Prière au Caire* [*Prayer in Cairo*] (1865). Although Gérôme traveled to Turkey and Egypt, his painting shows a distinctly European view of Muslim society.

ruler, known as the caliph (Arabic *khalifa*, literally “successor” [to the Prophet]), sometimes known as imam. This ruler was conceived of as the first among equals, appointed by at least the tacit consent of the people and granted legitimacy through the formal allegiance of the people of eminence and influence. The caliph was expected to rule his subjects through consultation with the learned among them, and his primary function was to uphold the religious law, maintain law and order in his realm, and fend off outside aggression. As far as their political duties were concerned, the ruled in return were expected to pay their taxes to the state treasury and be loyal to their ruler, so long as he obeyed the religious law. The first four caliphs after the death of Muhammad are idealized as the “rightly guided” because they are perceived to have observed the tenets of good governance, particularly in holding themselves accountable to the people. The period of the Rightly-Guided Caliphs and the constellation of virtues attributed to them had a lasting influence on the conceptualization of the Muslim polity and its governance. At the very least, it created an ideal against which the performance of later governments could be measured and criticized for failing to live up to it.

By the middle of the eighth century, however, the *ummah* had a legitimate caliphate based in Baghdad and a counter-caliphate in Muslim Spain. By the next century, lesser rulers by the title of sultan or emir had

emerged, often ruling their territories with some measure of autonomy. By the eleventh century, political theorists started to acknowledge these changed realities and recognized the possibility of having more than one ruler for the Muslim polity, provided that at least a large body of water separated them.

The office of the caliph survived many vicissitudes of fate. It greatly diminished in the wake of the Mongol depredations in Baghdad in the thirteenth century but resurged under the Ottomans in the sixteenth century. The Ottomans circulated the story that the last Abbasid caliph (the Abbasids ruled from 749/750 to 1258, with their capital in Baghdad) had transferred the title of the caliphate to them and thus they were entitled to assume the office themselves. The last Ottoman caliph was deposed in 1924 by the Republican Turks, who abolished the caliphate.

The caliph, as at least the titular head of the worldwide Muslim polity, manifested the symbolic unity of the Islamic realm. And despite the diversity of cultures and languages in different parts of the Islamic world that were often politically autonomous, there was indeed a unity in terms of shared religious observances, social customs, and a distinctive way of viewing the world. The term *Islam* refers not only to the religion but to a civilization with a specific yet varied constellation of values. Islamic civilization was (and largely remains) multicultural, multiethnic, and

multireligious. Not only Arabs, but Persians, Indians, Africans, Chinese, Malays, and others have been an integral part of it, as have Jews and Christians, in addition to Muslims. We call the civilization and its world Islamic because all these diverse peoples lived (and continue to a certain extent to do so) under the aegis of various Islamic administrations, not necessarily because they adhered to the religion of Islam. The inhabitants of the Islamic world did (and do) subscribe to certain common Islamic civilizational values and ideas, such as charity, hospitality, and patronage of learning, which created (and creates) a sense of group solidarity and a shared identity.

Dar al-Islam

The world of Islam was also conceived of in specifically territorial terms, especially by the medieval jurists. They coined the term *dar al-Islam*, referring to the “abode” or “territory of Islam,” opposed to which was the *dar al-harb*, the “abode” or “territory of war.” The celebrated jurist ash-Shafi’i (d. 820 CE) added a third category: the abode or territory of treaty or reconciliation. These concepts and terms are not to be found in the Qur’an or in the prophetic Sunna (sayings and practices of Muhammad); rather, they reflect the legal and political pragmatism of these jurists,

who wished to make sense of and impose moral order on the historical reality of their times.

In this, they were following a time-honored custom of defining themselves and the polity they inhabited by demarcating the limits of the civilized world as they knew it from the realm of disorder and moral chaos. Greeks in classical antiquity saw themselves as the very antithesis of all non-Greeks, whom they termed barbarians; similarly, the pre-Islamic Arabs set themselves apart from the uncivilized non-Arabs. Among earlier religious communities, the Jews separated themselves from the impure non-Jews, while Christians regarded the unsaved infidel as beyond the pale. For the Muslim jurists of this period, the territory of Islam represented all that was lawful and morally right in God’s world, being under the governance of God’s law. Beyond its confines, the rest of the world was in need of divine guidance and, ideally speaking, through propagation of the message of Islam or by acknowledging the suzerainty of the Muslim ruler, could in time (so it was hoped) be brought into the abode of Islam. Such a world vision was created by the spectacular spread of Islamic dominion in the few decades after the Prophet’s death, which tended to foster a sense of the inevitable and ultimate triumph of Islam. Such a worldview, however, did not include the forcible conversion of nonbelievers,

He who knows not and knows not he knows not: he is a fool—shun him. / He who knows not and knows he knows not: he is simple—teach him. / He who knows and knows not he knows: he is asleep—wake him. / He who knows and knows he knows: he is wise—follow him. • Arabic Proverb

strictly forbidden in the Qur'an (2:256), but only their political capitulation, preferably peacefully, but through military means if necessary.

Thus, although Egypt and Syria were conquered militarily by the Arabs in the late seventh century, the native populations remained largely Christian until about the tenth century. Similarly, the military conquest of the western Indian province of Sind was followed by the extension of the status of "protected people" (*ahl al-dhimma*) to Hindus, a status traditionally reserved under Islamic Law for Jews and Christians, which allowed them to continue to practice their Hindu faith in return for fealty to the new Muslim administration. Such imperial designs were not supported by all jurists; dissenting jurists and many ordinary pious Muslims were aghast at the notion of offensive military activity that could be justified by the invocation of an assumed confrontational bipolar world.

By roughly the twelfth century, these terms had begun to lose their efficacy and began to be redefined in response to changing historical and political realities. The Muslim polity had become quite fractured, having split into several autonomous realms with independent rulers who sometimes fought with one another. Muslims also sometimes traveled to non-Muslim territories and settled there. The question was posed: were these realms and Muslims no longer to be regarded as a part of dar al-Islam? In recognition of the changed situation, some jurists in this period formed the opinion that non-Muslim territory in which Muslims were free to practice their religion could be subsumed under the rubric of dar al-Islam. Thus, already in the medieval period, we see a broadening of the concept of the Islamic world to include not only countries and regions where Muslims predominated, but also territories that included minority Muslim populations who were not impeded in the practice of their faith. In a similar vein, in the contemporary era, the term *Islamic world* now includes not only the traditional heartlands of Islam, but also Europe and North America, both of which have sizeable minority Muslim populations. This may be understood to reflect a resurgence of the concept

of the worldwide *ummah*, signaling certain shared values and common religious observances among Muslims regardless of where they may be located and whether they are under the political jurisdiction of a Muslim ruler or not.

The Contemporary Islamic World

The vast majority of Muslims today are concentrated in southern and Southeast Asia, the Middle East, and northern Africa, with sizeable minority populations in the rest of Africa and Asia, Europe, and North America. Islam has been described as the fastest growing religion in the world today, with currently about 1.2 to 1.5 billion adherents, or approximately one-fifth of our world's population. Although the Islamic world is seemingly disparate and even divisive, it is still possible to speak of it as cohesive at a certain level.

Shared traumatic experiences under Western colonial rule have forged at least formal alliances among a number of the Islamic countries (and also with other underdeveloped or developing countries with similar experiences). Many in the Islamic world today continue to feel very vulnerable and under assault from secular modernity, economic globalization, and Western cultural mores, sometimes regarded as a continuation of the previous era of physical colonization, and thus termed neo-imperialism or neo-colonization. Elements in Islamic societies have become radicalized due to a sense of impotency vis-à-vis the status quo in the postcolonial world. These radical elements have attempted to assert a highly politicized and in some cases highly militant Islamic identity in an effort to resist Western-generated globalization and secularization, and, one might say, the economic and cultural "occupation" of the Islamic world. From time to time, these elements have caused and continue to cause great havoc both in their own societies, since they oppose many of the local ruling elites (whom they regard as the willing clients of the West), and beyond. The vast majority of the people in the Islamic world do not endorse their bloody tactics, although they may share their economic and political frustrations.

A worldwide body claims to speak on behalf of Muslim peoples everywhere today and may be regarded as a modern-day concretization of the nebulous concept of the *ummah*. This body, known as the Organization of the Islamic Conference (OIC), established on 25 September 1969 in Rabat, Morocco, has fifty-seven members as of 2010 that represent countries with majority Muslim populations, plus thirteen observer states. The OIC website recognizes “the concrete expression of a great awareness, on the part of the Ummah, of the necessity to establish an organization embodying its aspirations.” Moreover, the OIC represents the desire on the part of the member states to “speak with one voice to safeguard the interest and ensure the progress and well-being of their peoples and those of other Muslims” throughout the world. The political leaders of the member states meet once a year in a major Islamic capital city. Certainly, the OIC may be regarded as a microcosm of the Islamic world, seeking to define a commonality of interests, mediate internal conflicts, and articulate a unified position on many current issues and political disputes. In recent years, the OIC has taken specific stands on global issues such as the Persian Gulf War, the United Nations’ peacekeeping efforts in Bosnia and Herzegovina, and the reconstruction of Afghanistan. Its effectiveness in both intra-Muslim affairs and global politics has been marginal to date but the OIC retains credibility as the sole organization which publicly articulates universal Islamic claims and aspirations and attempts to make them part of the global discourse.

Islands

Islands are almost as diverse as they are numerous: large or small, rich or poor, inhabited or populated. From the earliest times, as populations settled ever farther around the globe, humans have coveted islands as stepping stones and colonies. Islands have served as trading posts, warehouses, naval bases, and refueling stations. They are still valued today for their often exotic environments and remote locales.

Geographers tell us there are 5,675 islands on the Earth measuring from 10 square kilometers (3.86 square miles) to 1 million square kilometers (3.86 million square miles), plus almost another eight million smaller islets. Islands cover only 7 percent of the planet's surface but hold 10 percent of its population and constitute 22 percent of its sovereign states, whose claims to territorial waters extend to a quarter of the oceans.

Islands are almost as various as they are numerous. A "continental" island is part of a continental shelf (Great Britain and Ireland, for instance, are continental islands attached to the European continental shelf); "oceanic" islands are the product of deep sea volcanic eruptions. Some islands stand alone; others belong to archipelagoes. Islands host a vast range of flora and fauna. There are islands that have never been inhabited and those that have seen a sequence of occupations. There are tropical and arctic islands whose temperatures remain about the same year round and temperate islands that experience changing seasons. There are islands linked to the mainland by bridges and tunnels and islands that can only be reached by water or air. Economically, there are poor

and rich islands, islands that are sovereign and those that are dependent on other nations. Islands come in all kinds of political persuasions, from democracies to dictatorships. Britain and Japan can be considered the two most prominent island nations in world history, but many islands have attained levels of development that are the envy of mainlands.

Defining Islands

Despite their variation, we tend to stereotype islands. Their history and geography have been defined by mainlanders, who are in the habit of thinking of them as uniformly small, peripheral, remote, isolated, and timeless. Islands and islanders have suffered the enormous condescension of continents. Up to the fifteenth century, Western geographers considered the world to consist only of islands—one large one, *Orbis Terrarum*, and many smaller ones. Early European explorers assumed that every land they encountered was an island, and it was not until the sixteenth century that continents and islands were finally distinguished from one another, islands being defined as any land completely surrounded by water.

Even now it is hard to separate islands from continents, as the latter are also seagirt (surrounded by the sea), and there has been a systematic questioning of the metageography of both islands and continents. It is now clear that islands have never been wholly peripheral or remote—nor have they been isolated or static. Considering them in the context of history reveals what a huge role islands have played in every stage in the mental as well as physical development of humanity. The species we know as *Homo sapiens* originated at the edge of the sea.

The South Island of Cies, in Galicia, as seen from the island of Faro. Fascination with islands (*islomania*) is a cornerstone of the modern tourist industry.

Once humans left east Africa behind, they began a process of island hopping that did not end until the whole Earth was occupied. Water has been the greatest facilitator of human movement and contact, an advantage that explains why islands have often been at the forefront of development. Prehistoric foragers used islands as fishing camps and trading posts. The fruits of the inland agriculture revolution in the Levant (eastern Mediterranean region) were transferred to Europe by way of the island of Cyprus about 6000 BCE.

Island Importance

Islands were vital to the ancients' mastery of the Indian Ocean and the Mediterranean Sea, where Phoenicians and then Greeks established colonies on islands. The first conquest of the Pacific, which began in remote Oceania about 4000 BCE, and was completed on the shores of New Zealand in 700 CE, was accomplished by island hopping. Pacific islanders think of themselves as occupying a great sea of islands they consider not at all remote or peripheral. Atlantic voyaging came much later but was accomplished in a similar manner. The Vikings island-hopped, and, had Columbus not imagined the sea to be filled with islands (most of them legendary), he would never have set out westward. He was

so convinced he had reached the offshore islands of India, that he misnamed the Caribbean Islands the West Indies. Until the early nineteenth century, searches for a sea route to India were inspired by the idea that North America was archipelagic and therefore passable by water.

From the earliest times, islands have been coveted as colonies. The Phoenicians and Greeks used them as access points to hinterlands. The European seaborne empires of the sixteenth and seventeenth centuries all used islands extensively. They served as fishing stations and fur trading posts. Sugar planting was transferred from the isles of the Mediterranean to the Madeiras and Canaries, and then to the Caribbean. Trading for slaves from the islands off the west coast of Africa made it unnecessary for Europeans to risk their health in the tropical interior. As European empires spread to the Indian and Pacific oceans, islands were vital as entrepôts (intermediary centers of trade and transshipment), victualing stops, and naval bases. For the next years, they were the most fought over properties in the world, at the very center of commercial, capitalist development. By the eighteenth century, the Atlantic had become its own sea of islands, brought close together by advances in navigation and a shared cosmopolitan culture. Until the nineteenth century, continents—not islands—were truly insular.

A self does not amount to much, but no self is an island; each exists in a fabric of relations that is now more complex and mobile than ever before. • Jean-Francois Lyotard (1924–1998)

Cultural Significance

Islands have played an exceptionally large role in Western minds. They have long been the object of spiritual quests, both pagan and Christian. They have frequently been identified with paradise, but also with hell (as in the case of the Galapagos Islands as described by Herman Melville). Thomas More used a fictional island to envision the first great utopia. William Shakespeare chose an island as the setting for his play, *The Tempest*, while Daniel Defoe's famous novel, *Robinson Crusoe*, is about a sailor shipwrecked on an island. Anthropology got its start on islands that served as laboratories for the naturalists Charles Darwin and Alfred Russel Wallace, founders of the science of evolution. Fascination with islands, sometimes referred to as *islomania*, continues to be a major theme in Western culture, and is a cornerstone of the modern tourist industry.

But even as the cultural significance of islands increased, their economic and political centrality declined. In the nineteenth century, the shift from commercial to industrial capitalism coincided with the rise of continents at the expense of islands. The new industrial cities were located on mainlands. The end of slavery in the nineteenth century produced a labor crisis in many island plantation systems. With the rise of steam power and the spread of railroads, the age-old advantage of water transport was much diminished. The value of islands as entrepôts, victualing stops, and fishing stations declined. In the twentieth century, islands all around the world lost population. Politics as well as economies of scale put islands at a disadvantage. In the wave of decolonization that followed World War II, many islands became politically independent only to find that they were still economically tied to their old imperial masters. In the postwar era, islands came to be seen as peripheral, isolated, and backward.

Island Challenges

Islands today find themselves challenged in a number of ways. Of all Earth's land forms, they are most

affected by rising sea levels and the frequency of storms caused by global warming. They continue to lose population to mainlands. Islanders constitute one of the world's largest diaspora populations, and many islanders left behind by relatives striking out for new lands are dependent on private remittances for survival. (Cuba's economy, for instance, has long depended on remittances, many of which are sent from Cuban Americans; the U.S. government placed further caps, in 2004 and again in 2009, on the amount allowed, and tightened standards so that remittances can be sent only to immediate family members.) On the other hand, islands have seen an in-migration of tourists and mainlanders looking for holiday homes. Assisted by bridge and tunnel building, this influx has led to the gentrification of islands nearest to mainland population centers. While the new arrivals come seeking the "island way of life," older residents fear the disappearance of *their* way of life.

Connectivity

In earlier phases of globalization, islands were often the facilitators of international trade and economic development. Today, they continue to play this role, though in a different manner. The world's largest single industry—tourism—is heavily dependent on them. Their offshore locations make them ideal headquarters not only for legitimate multinational businesses but also for drug smugglers, pirates, and spy operations. As so much of the world's commerce is carried by ship, their importance as naval and air bases is again growing. Because of their small size, many islands have proved exceptionally nimble in adopting new technologies. But, as the experience of Iceland has shown, when islands become models of interconnectivity they can become vulnerable to world economic crises. Iceland's economic boom, low unemployment, and relatively equal distribution of wealth—a result of the rapid global expansion of its financial sector in the early 2000s—proved unsustainable; exposure to the world market resulted in the sharp depreciation of the krona and the subsequent failure of Iceland's three largest banks in 2008.

Today, few islands are truly remote, peripheral, or insular. Islands certainly do not exist in stasis. It no longer makes sense to distinguish islands and continents or to stereotype them or their inhabitants. The Earth is itself can be seen as an island in a larger universe. Its inhabitants occupy a sea of islands, some large, some small, but all intensely interconnected and interdependent. The future of both mainlands and islands depends on how well that fact can be reconciled. Only by viewing islands in the proper context of world history can their agency and significance be appreciated.

Jainism

The cosmology of Jainism, originating in India as early as the sixth century BCE, asserts that karmic particles adhere to the soul and obstruct its true nature. Through acts of benevolence, and by adopting a strict moral code of nonviolence (*ahimsa*), some 4 to 6 million practitioners of Jainism today—mainly in India, eastern Africa, Britain, and North America—seek to shed their karmic burden.

The Jaina tradition arose in India more than 2,500 years ago. The great Jaina teacher Mahavira Vardhamana (c. 500 BCE) was a contemporary of the Buddha, and both taught a doctrine grounded in renunciation of worldly concerns. Starting around 300 BCE, two strands of Jainism arose: the Digambara group, found mainly in south and central India, and the Svetambara group, found mainly in western and northern India. The Digambara require total nudity for their most advanced monks and claim that women must be reborn as men to achieve liberation (*kevala*). The Svetambara allow their monks and nuns to remain clothed in white and allow for the possibility of women's ascent to the highest spiritual realms. Most Jaina follow a lay life and have excelled in business, particularly in publishing, pharmaceuticals, the diamond trade, marble, and textiles. Although many Jaina self-identify with the larger Hindu tradition, census figures place the Jaina population at between 4 and 6 million.

Jainism emphasizes the teaching of nonviolence (*ahimsa*). According to the tradition, karmic particles adhere to the soul, obscuring its true nature. By the progressive application of five ethical vows, one is able to diminish and eventually expel the influence of karma, resulting in spiritual liberation. Twenty-four

great teachers (*tirthankara*) are said to have attained this goal and set an example for others through their teachings; the first is known as Adinath, or Rishibha, who is said to have established agriculture, kingship, marriage, and the spiritual path. Mahavira is the most recent; his immediate predecessor was Parshvanatha (c. 800 BCE).

The earliest extant Jaina text is the *Acaranga Sutra* (c. 400 BCE), written in the Prakriti language and revered by the Svetambara community. It provides detailed instructions on how to practice the five great vows: nonviolence (*ahimsa*), truthfulness (*satya*), not stealing (*asteya*), celibacy (*brahmacharya*), and nonpossession (*aparigraha*). Both traditions agree on the intricate Jain theory of karma and cosmology outlined by the scholar Umasvati in his *Tattvartha Sutra*, a Sanskrit text written in the fifth century BCE.

Umasvati's *Tattvartha Sutra* proclaims that countless individual life forces (*jiva*) have existed since the beginning of time. They take many interchangeable forms and are found in the four elements of earth, water, fire, and air, as well as in microorganisms (*nigodha*), plants, and animals. At the point of death, the life force moves from one body to the next, depending on its karmic constitution. The goal of Jainism entails an elevation of consciousness about one's karma, leading to birth in a human body, and the adoption of a nonviolent lifestyle that will ultimately free a person from all karmic entanglements. At this final stage of blessedness, one ascends to the realm of perfection (*siddha-loka*) wherein one dwells eternally observing the machinations of the world but never again succumbing to its allurements. All twenty-four great teachers of Jainism are said to have attained this state, along with an undetermined number of saints.

I adore so greatly the principles of the Jain religion that I would like to be reborn in a Jain community. • **George Bernard Shaw (1856–1960)**

Umasvati categorized forms of life hierarchically according to the number of senses they possess. The lowest realm, Earth organisms and microorganisms, as well as plants, possess only the sense of touch. Earthworms and mollusks have as well the senses of taste and touch. Crawling insects have, in addition, a fourth sense: smell. Moths, bees, and flies add a fifth: sight. The Jaina place animals that can hear—and those that can hear and think, including reptiles, birds, and mammals—at the highest realm. As such, these life forms develop moral agency, and can make clear decisions about their behavior. Jaina cosmology imbues all aspects of the world that surrounds us with feelings and consciousness. The earth we tread upon, the water we drink, the air we inhale, the chair that supports us, the light that illumines our day—all these entities feel us through the sense of touch, though we might seldom acknowledge their presence. Humans, as living, sensate, sentient beings, have been given the special task and responsibility of growing in awareness and appreciation of these other life forms, and acting accordingly. Humans have the opportunity to cultivate ethical behavior that engenders respect toward the living, breathing, conscious beings that suffuse the universe. Consequently, the Jaina community maintains thousands of animal shelters (*pinjrapole*), particularly in western India.

The Jaina tradition emphasizes in great detail the perils of karma and urges people to avoid all forms of harm. A traditional tale warns against the wanton destruction of trees, while simultaneously explaining the mechanics of karma:

A hungry person with the most negative black *lesya* karma uproots and kills an entire tree to obtain a few mangoes. The person of blue karma fells the tree by chopping the trunk, again merely to gain a handful of fruits. Fraught with gray karma, a third person spares the trunk but cuts off the major limbs of the tree. The one with orangish-red karma carelessly and needlessly lops off several branches to reach the mangoes. The fifth, exhibiting white or virtuous karma, “merely picks up ripe fruit that has dropped to the foot of the tree.” (Jaini 1916, 47)

Trees were not to be regarded covetously for their fruits, but like all life forms were to be given respect and treated without inflicting harm. This ethic of care was to be extended to the entire biotic community, engendering awareness of and sensitivity to the precious nature of life.

During the period of the Islamic incursion into India, the Jaina community was often in retreat, with some of its temples taken over and converted into mosques. Some Jaina monks, however, helped exert nonviolent influence within the Islamic world. In 1591, Jinacandrasuri II (1531–1613), a leader of the Khartar Gacch of the Svetambaras, traveled to Lahore, where he greatly influenced the Mughal emperor Akbar the Great. He gained protection for Jaina pilgrimage sites, as well as legal protection ensuring that Jain ceremonies would not be hindered. He even lent support to Jaina advocacy for animals, and forbade the slaughter of animals for one week each year.

Mohandas Gandhi (1869–1948), who liberated India from British colonialism through the enactment of nonviolent principles, was deeply influenced by the Jaina tradition. He eschewed all forms of violence and even titled his lengthy autobiography after the second Jaina vow: *Satyagraha or My Experiments with Truth*. He learned of Jainism during his childhood in Gujarat, an Indian state with a large Jaina presence, and from Raichandra, a prominent Jaina lay-teacher.

Another modern-day example of Jaina activism can be found in the work of Acharya Tulsi (1914–1997) and his successor, Acarya Mahaprajna, both leaders of the Svetambara Therpanthi movement. In June of 1945, deeply disturbed by World War II, he issued a nine-point declaration of the basic principles of non-violence including guidelines for both individuals and governments.

The Jaina community remained almost exclusively within India until the twentieth century, when many Jaina migrated to eastern Africa, Britain, and North America. Today, this diaspora community tends to identify readily with values centered on environmental protection. The classics and religion professor Anne Vallely notes that “rather than through the idiom of

self-realization or the purification of the soul, ethics are being expressed through a discourse of environmentalism and animal rights” (2000, 193). These values are expressed through such journals as *Resurgence*, edited by the former Jaina monk Satish Kumar, and *Jain Spirit: Sharing Jain Values Globally*, edited by a Jaina lay-scholar, Atul Shah. Extensive websites buttress the new global reach of the Jaina community, which continues to espouse vegetarianism and animal activism as key components of its ethical expression.

Jaina cosmology asserts that the world consists of myriad souls all seeking their own way. Through mistakes of karma, their karma becomes thick and entrenched. Through acts of benevolence, their karmic burden becomes lighter. By the adoption of a strict moral code grounded in nonviolence, the Jaina seek to shed their karmic cloak. This practice requires a clear understanding of what constitutes life, and how one can cultivate care and concern in one’s encounters with all forms of life. By careful dietary observance and restriction of acquisitiveness, the soul gradually detaches itself from the clutches of karma. This process also benefits others, in that through the abatement of one’s greed, others can live more

freely. As age-old problems of human conflict and more contemporary problems of environmental mismanagement become more pressing, the abstemious lifestyle offered by the Jaina may become increasingly instructive to those seeking peace and environmental protection.

Japanese Empire

In response to European and American domination in Asia in the late nineteenth century, Japan developed an industrial economy and a strong military to build its own empire, which grew to incorporate much of East Asia, Southeast Asia, and the South Pacific. Japan's defeat in World War II resulted in the loss of its overseas territories, the destruction of much of its homeland, and occupation by a foreign power.

When Emperor Meiji ascended Japan's imperial throne in 1868, Europeans and Americans were conquering, buying, co-opting, or otherwise dominating many areas of Asia. In order to protect their country from the threat posed by these Western imperial powers, Japan's leaders established and consolidated their national boundaries in the 1870s by incorporating the large northern island of Hokkaido (home of the Ainu people), Okinawa and the Ryukyu Islands to the south, and the smaller Bonin Islands to the southeast within Japan's long-established territorial space of Honshu, Shikoku, and Kyushu islands. They also encouraged an emergent sense of imperial nationalism, and the government adopted the slogan "rich nation, strong army" (*fukoku kyohei*) while developing an industrial economy and creating a strong military based on Western strategy and Western weapons. Japan's newly refurbished military forces were initially used against internal rebellions, but its first real test was on the Asian continent.

Korea and the First Sino-Japanese War

Japan's leaders had long considered the Korean peninsula a strategic area needing diplomatic attention

and possibly military control. Korea's geographic proximity made it both vulnerable and potentially threatening. In 1274 and 1281 Mongol ruler Kublai Khan (1215–1294) attempted invasions of Japan from Korea, and in the 1590s the Japanese warlord Toyotomi Hideyoshi (1536/7–1598) launched two invasions of Korea, causing massive death and destruction.

Nominally led by the native Yi imperial family, Korea had a tributary relationship with China that allowed Qing imperial rulers in Beijing to control Korea's foreign affairs. Russia was interested in Korea as a Pacific Ocean terminus for its mammoth Trans-Siberian Railroad. Japan forced a commercial treaty and then a political treaty on Korea (with China's reluctant acquiescence) in 1876 and 1884. Nevertheless, the much larger countries of China and Russia remained potential threats to Japan's strategic interests in Korea. When the internal Tonghak Rebellion grew too large for the Korean government to handle in 1894, they called in Chinese troops. Alarmed, the Japanese army immediately landed its own troops on the Korean peninsula, and war soon broke out between China and Japan. The Chinese and Korean forces were no match for Japan's modern troops and weapons.

The Treaty of Shimonoseki and the Triple Intervention

As a result of the Treaty of Shimonoseki (1895) that ended the war, China paid Japan a hefty indemnity, Korea was declared independent of Chinese control (and thus easier for Japan to influence), and Formosa (present-day Taiwan) and the Liaodong Peninsula,

The Yasukuni Shrine in Tokyo, founded in 1869 by the Meiji emperor, is dedicated to the spirits of those who lost their lives serving imperial Japan, especially during wartimes. GNU GPL License.

in northeastern China across the Korea Bay from Korea, were ceded to Japan. But the treaty's terms upset Russia, Germany, and France, who did not want Japan firmly entrenched on the strategically important peninsula close to their own treaty areas in China. They demanded that Japan return the Liaodong Peninsula or face war against the three of them. Russia, the driving force behind this "triple intervention," also did not want to allow Japan more territory bordering its interests in Manchuria. Unable to gain support from the British or Americans to counter the triple intervention, Japan grudgingly gave in.

Nevertheless, this first successful overseas test of Japan's newly modernized military, followed by its participation in suppressing China's anti-foreign Boxer Rebellion of 1900–1901, demonstrated to Japan's political and military leaders the weakness and disarray of the once mighty China—vulnerabilities that Japan would later exploit more fully.

The Russo-Japanese War of 1904–1905

Still smoldering over the triple intervention and subsequent occupation of the Liaodong Peninsula by Russian troops, Japan launched a surprise attack against Russia on 8 February 1904, sinking most of Russia's Asian fleet at Port Arthur on Liaodong. Two days later, Japan declared war. Japanese and

Russian ground troops fought difficult, bloody battles, with Japan finally taking the important junction of Mukden (Shenyang), directly north of the Liaodong Peninsula, in March 1905. In May 1905, Russian naval forces sent from the Baltic were devastated by the Japanese navy, led by Admiral Togo Heihachiro (1848–1934), at the Tsushima Straits. Defeated on land and especially at sea, and having to deal with anti-Czarist revolution at home, the Russian imperial government agreed to peace negotiations with Japan. The Russo-Japan War, concluded by the Portsmouth Treaty of 1905, and mediated by U.S. president Theodore Roosevelt, was a tremendous victory for Japan. Japan regained the Liaodong Peninsula, Russian interests in southern Manchuria were transferred to Japan, the southern portion of Sakhalin Island was ceded to Japan, and Korea was recognized as under Japan's political and economic control. Japan declared Korea a protectorate territory in 1905 and formally annexed the peninsula in 1910. A nonwhite country militarily defeating a major Western and largely white country was disturbing for Westerners, with their entrenched notions of racial superiority. In Japan, by contrast, the war led to a dramatic upsurge of nationalist sentiment, and across East Asia Tokyo was regarded as a mecca for young, energetic Asians who wanted to learn how to build an economy and military that could stand up to the West.

The bowing Chinese indicate they've given up the battle at the end of the First Sino-Japanese War.

Japan's Empire During World War I

Japan entered World War I (1914–1918) on the side of the Allies (Britain, France, Russia, the United States, and Italy) because of the Anglo-Japanese Alliance of 1902. Japan supplied the Allies with armaments and nonmilitary supplies, but took no active part in the war in Europe. Japan did use its military forces, however, to occupy German-controlled islands in the South Pacific and occupied the Shandong territory in China previously controlled by Germany. Japan also issued the “Twenty-One Demands,” a set of political, economic, and military concessions it demanded from China. China received little outside help from the Allies, who were preoccupied with the war in Europe, and was forced to agree to a slightly reduced set of Japanese demands.

Immediately after King Kojong (1852–1919), the last Korean emperor, died, many Koreans planned a peaceful demonstration against Japanese rule to coincide with the funeral ceremonies on 1 March 1919. Japanese colonial authorities in Korea, drawn primarily from military forces, brutally crushed the largely peaceful demonstrations. Approximately seven thousand Koreans were killed and tens of thousands were injured. Barely two months later, on 4 May, anti-Japanese sentiment exploded in China

when the Paris Peace Conference announced that Japan would maintain control of Shandong. Chinese university students, workers, shopkeepers, writers, and artists participated in marches, demonstrations, and anti-Japanese boycotts in Beijing and throughout many of China's cities for several days before order was restored. These two events became important nationalist symbols for generations of Koreans and Chinese, respectively.

The Washington Conference and the 1920s

In order to deal with territorial, economic, and military disarmament issues that the Paris Peace Conference bypassed, some of the Allied powers met in Washington, D.C., from December 1921 to February 1922 to hammer out a series of agreements. The United States, Britain, France, and Japan first agreed to a “Four Power Pact” confirming the status quo regarding one another's Pacific territories. Next, the United States, Britain, Japan, France, and Italy agreed on a “Five Power Treaty” limiting the construction of naval capital ships—battleships and cruisers. Japan reluctantly agreed to this naval limitation treaty after receiving assurances it could substitute newer ships in the planning stages for older ships slated for decommissioning. Participants also agreed to a “Nine

Power Treaty” guaranteeing the territorial integrity of China and establishing an “open door” policy that granted all signatories equal economic opportunities in China.

The agreements of the Washington Conference were substantial and limited military construction and military confrontations among the major powers for a decade or more. Nevertheless, many nationalists in Japan believed the treaties adversely affected Japan’s imperial interests and claimed their representatives to the conference did not adequately consult the military—even though one of the three Japanese representatives was the highly decorated Admiral Kato Tomosaburo (1861–1923). At the London Naval Conference in 1930, the naval limitations treaty was renewed despite strenuous opposition from the Japanese navy. Hamaguchi Osachi (1870–1931), the prime minister who forced Japan’s parliament (the Diet) to accept the treaty, was assassinated by a civilian ultranationalist.

Meanwhile, the U.S. Congress approved the Oriental Exclusion Act as part of its 1924 Immigration Bill. As a result of the new law, Japanese immigrants were excluded from the United States and its territories, including Hawaii. Both the Japanese ambassador to Washington and the U.S. ambassador to Tokyo resigned in protest. The Oriental Exclusion Act raised nationalism in Japan to a dangerous level, and significantly damaged United States-Japan relations for many years.

Manchuria-Manchukuo

Japan had long been interested in Manchuria for its raw materials (especially mineral resources), agricultural goods, as a destination for Japanese immigrants, and as a strategic buffer between Japan’s Korean colony and China and Russia. Despite attempts by Japan’s foreign minister Kijuro Shidehara (1872–1951) to promote Japan’s interests on the Asian continent through conciliatory means, ideological and military hardliners used the rising tide of nationalism and the economic problems of the 1920s to agitate for more direct intervention. In June

1928, members of the Japanese army stationed on the Liaodong Peninsula assassinated Zhang Zuolin (1873–1928), the Chinese warlord controlling most of Manchuria. Then in September 1931, Japanese soldiers blew up a section of the South Manchurian Railway near Mukden. Claiming the explosion was set by Chinese troops, Japanese troops took Mukden, and with reinforcements sent from Korea fought and occupied most of the important cities and areas along the South Manchurian Railway. Japanese troops in the field ignored orders from superiors in Tokyo to cease fighting, continuing until most of Manchuria was occupied.

The Japanese government in Tokyo reluctantly accepted this *fait accompli* and declared Manchuria the “independent” nation of Manchukuo in early 1932. The League of Nations refused to accept Manchukuo as an independent nation and condemned Japan’s actions in Manchuria. In response, Japan quit the League of Nations.

Manchukuo was ostensibly led by Pu Yi (1906–1967), the last emperor of China, who had abdicated in 1912. However, the administration of the country was controlled by Japanese military and civilian officials, with Japanese forces in charge of security. The South Manchurian Railway Company and the Manchurian Heavy Industries Corporation led economic development efforts in the region and promoted Japanese immigration to Manchuria. Manchukuo was seen by many Japanese officials as “the jewel in the crown” of their empire.

Assassinations and Military Control

Japan’s increasing nationalism, coupled with the severe economic problems caused by the worldwide depression following the October 1929 stock market crash on Wall Street and the controversy over Manchuria, led to assassinations of prominent business and political leaders and military domination of the Japanese government. In early 1932, the head of the Mitsui conglomerate was assassinated, as was the former governor of the Bank of Japan (then serving as finance minister), both by a civilian ultranationalist

This lithograph depicts the first battle of the Russo-Japanese War (1904–1905). Library of Congress.

group. Those killings were followed by the assassination of Prime Minister Inukai Tsuyoshi (1855–1932), whom young army and navy officers killed because he had voiced opposition to the army's actions in Manchuria.

On 26 February 1936, young Japanese army officers who wanted to restore rule to the emperor led more than a thousand soldiers in an attempted coup of the Japanese government. They assassinated four top officials, including the finance minister, and only narrowly missed the prime minister. The attempted coup was stopped after four days when Emperor Hirohito (1901–1989; reigned 1926–1989) made clear that he was opposed to what coup leaders were doing in his name. The overall effect of the assassinations of the 1930s, however, was to stifle civilian complaints about the military in general and especially political dissent concerning the military's expanding operations on the Asian continent.

The Second Sino-Japanese War, 1937–1945

On 7 July 1937, a shooting incident between Japanese army troops and Chinese troops near the Marco Polo Bridge outside of Beijing soon led to full-scale war in China. By the fall, Japanese troops were fighting Chinese Nationalist (Guomindang) troops in Shanghai, where they killed thousands of Chinese civilians.

After capturing Nanjing, the Nationalist capital, in early December 1937 Japanese troops went on a rampage of slaughter and rape. Chinese troops were summarily executed after surrendering. But the vast majority of those killed were civilians—old men, women, and children. The number killed by Japanese troops in the area of Nanjing from December 1937 to February 1938 is still a matter of considerable controversy. Based on eyewitness reports from

In this cartoon from *Osaka Puck* (December 1942), Japan shakes hands with a dark-skinned native of Indonesia while the frightened woman, representing Dutch colonialism, runs away.

surviving Chinese, Western missionaries, and even from Japanese soldiers who participated in the massacre, the Tokyo War Crimes Trials following World War II calculated the number of Chinese deaths at Nanjing to be more than 200,000—one of the worst atrocities of the twentieth century.

By the end of 1938, the Japanese military controlled most of the eastern region of China and began running the area as an informal colony. The Japanese convinced former Nationalist leader Wang Jingwei (1883–1944) to head the puppet government there. Meanwhile, the Chinese Nationalist leader Chiang Kai-shek (1887–1975) and his forces set up their wartime government and military headquarters at Chongqing, a city deep in China's heartland and protected from large-scale Japanese attacks by wide rivers and mountains. The Chinese Communists, led by Mao Zedong (1893–1976), became increasingly effective with guerrilla-style attacks against Japanese forces.

By 1941, it was clear that despite Japan's military superiority, the vast geographic area of China and its enormous population united against the Japanese made the prospects of Japanese victory dim. In China and Manchuria, Japanese military operations were consuming ever larger amounts of oil, steel, rubber,

and food. In 1939 Japanese forces tried to gain access to more raw materials by pushing north into Soviet-controlled Mongolia but suffered heavy losses at Nomonhan before reaching a cease-fire agreement. Military and political leaders in Tokyo then made a fateful decision to advance into Southeast Asia.

The Pacific War, 1941–1945

In response to Japanese military actions in China, the U.S. government prevented first Japanese purchases of scrap metal, then aviation fuel, then all oil, and in the summer of 1941 froze all Japanese financial assets in the United States.

To gain raw materials to sustain their military operations in China and to maintain Manchukuo, Japan's leaders decided to advance south into Indochina (Vietnam, Cambodia, and Laos) and especially to the resource-rich Dutch East Indies (present-day Indonesia). Following two unsuccessful rounds of negotiations with the United States, planes from Imperial Japanese Navy carriers attacked battleships, aircraft, and other military facilities at the U.S. Pacific Fleet Headquarters at Pearl Harbor, Hawaii, on 7 December 1941. Japanese armed forces simultaneously

attacked Hong Kong, Malaya, the Philippines, Guam, and Wake Island. Japan's war in China was now combined with a Pacific war against the Americans and their Western allies.

Japanese military forces scored one victory after another for several months and controlled much of Southeast Asia by the spring of 1942. At this point, the Japanese Empire was at its largest dimension and formally combined into a pan-Asian organization called the Greater East Asia Co-Prosperity Sphere. Despite slogans of brotherhood such as "Asia for Asians," the reality for people living in the Great East Asia Co-Prosperity Sphere was one of Japan as a demanding, harsh imperialist power.

Japanese leaders hoped the Americans, having their hands full trying to stop Hitler in Europe, would quickly come to an agreement that would allow Japan to maintain its presence on the Asian continent. The surprise attack on Pearl Harbor, however, plus the surrender and Bataan Death March of American and Filipino forces in the Philippines, infuriated Americans so much that they would settle for nothing less than unconditional surrender from Japan. Starting with sea battles at Coral Sea and Midway in June and July 1942, the tide began to turn against the Japanese. In October 1944, when the Battle of Leyte Gulf destroyed what

then remained of the Japanese Imperial Navy, it was clear Japan would lose the Pacific War. The only question was when.

Tragically, Japanese military and political leaders refused to surrender even after large-scale U.S. bombing of major Japanese cities began in late 1944. They resorted instead to using young, inexperienced pilots for *kamikaze* suicide attacks. Even the terrible destruction and loss of 100,000 civilian lives in the Tokyo firebomb raid of March 1945 and the larger loss of Japanese military and civilian lives on Okinawa shortly thereafter failed to convince Japan's leaders to surrender. After the early August atomic bombings of Hiroshima and Nagasaki and the Soviet invasion of Manchuria, Emperor Hirohito finally surrendered, with an announcement broadcast throughout the Japanese Empire on 15 August 1945.

Legacy of the Japanese Empire

Starting with the acquisition of Taiwan following its victory in the Sino-Japanese War of 1894–1895, Japan's empire grew to incorporate much of East Asia, Southeast Asia, and an extensive area of the South Pacific. Motivated to varying degrees by strategic and economic considerations as well as by a nationalist

desire for international glory that sometimes included a mystical sense of destiny and racial superiority, Japan's empire building during the first half of the twentieth century was not unlike that of several Western countries during the nineteenth century. Ultimately, however, the expansion and brutality of the Japanese Empire provoked a devastating war. After its defeat, Japan lost all the overseas territories it had gained since 1895, suffered the destruction of much of its homeland, and was occupied by a foreign power for the first time in its history. Even some sixty years later, Japan continues to encounter hostility from the peoples and nations it conquered during its era of imperialism.

Jefferson, Thomas

(1743–1826)

THIRD U.S. PRESIDENT

Thomas Jefferson, the main author of the American Declaration of Independence, drew upon French and English Enlightenment political philosophy, and especially the work of the Englishman John Locke, to urge colonists to fight for a government based on popular consent—a government that could secure the right to life, liberty, and the pursuit of happiness. Jefferson became the third U.S. president in March 1801.

Thomas Jefferson was the main author of the American Declaration of Independence, issued in 1776, which inspired the American Revolution and many anti-colonial movements across the globe. Jefferson also became the third president of the United States in 1801 and purchased land known as the Louisiana Territory from the French in 1803, doubling the size of the new nation and setting the stage for the growth of the U.S. as the dominant power in the Americas.

Jefferson was born on 13 April 1743 in the British colony of Virginia in North America. His parents were tobacco planters and part of the colonial elite. In 1760 he enrolled in the College of William and Mary in Williamsburg, Virginia. Upon graduation, he earned a living as both a lawyer and a farmer, living on his plantation, Monticello, in Virginia. In 1772 he married Martha Wayles Skelton, a widow, who died ten years later. Jefferson served as a member of the House of Burgesses, the lower house of Virginia's legislature, from 1769 to 1775 and became a leader of the developing opposition to British policies.

In 1776 the members of the Second Continental Congress selected a committee to draft a declaration of independence and Jefferson became the principal

author. The Declaration, adopted by Congress on 4 July, announced the birth of a new nation, listed specific grievances against the British king George III, and set forth a philosophy of natural rights. Drawing upon French and English Enlightenment political philosophy, and particularly the work of Englishman John Locke, Jefferson urged the colonists to fight for a government based on popular consent that could secure the right to life, liberty, and the pursuit of happiness. The Declaration, and the American Revolution it inspired, generated a wave of revolutionary sentiment throughout Latin America and Western Europe in the nineteenth century and were even used to justify anti-colonial struggles in Asia and Africa in the twentieth century.

Nevertheless, Jefferson, and the new nation he helped to create, did not live up to the ideals annunciated in the Declaration of Independence. He favored government run by prosperous white men and saw those without property, women, Native Americans, and African American slaves as incapable of governing and undeserving of equal rights. Jefferson owned a number of slaves and probably fathered some with one of his slaves. The words of Jefferson, however, would later be used by the excluded to demand political equality in American society.

Jefferson went on to play a major role in the development of the United States. He drafted the bill that established religious freedom and the separation of church and state in Virginia. He served as Virginia governor from 1779 to 1781 and worked as U.S. minister to France from 1785 to 1789. Upon Jefferson's return home in 1789, President George Washington selected him to become the first secretary of state. Jefferson became a strong advocate for a

Gilbert Stuart, *Thomas Jefferson* (c. 1821). Oil on canvas.

weak central government and an economy based on agriculture. The secretary of the treasury, Alexander Hamilton, favored a strong federal government and an industrialized economy. Jefferson's hopes for the new nation resulted in the creation of the Democratic-Republicans in Congress, and Hamilton's vision in the formation of the Federalists—the first political parties in U.S. history. After Jefferson's term as secretary of state ended in December 1794, and Hamilton resigned from public office and returned to his legal practice in New York in 1795, these two parties continued to dominate political thought for the next thirty years. After Washington refused a third term as president in 1796, Jefferson stood for election against John Adams. Adams won and became the second

president of the U.S., and Jefferson came in second and became the vice president.

In the 1800 presidential contest Jefferson tied with fellow Republican Aaron Burr in the electoral college, but the House of Representatives settled the tie in favor of Jefferson and he became president and Burr vice president of the United States. Jefferson took office in March 1801 and served as president for two terms. As president, Jefferson's major accomplishment was the acquisition of the Louisiana Territory from France in 1803. The Louisiana Purchase, which extended from the Mississippi River to the Rocky Mountains and from the Gulf of Mexico to Canada, roughly doubled the size of the United States and set the nation on a path of westward expansion. Jefferson died on 4 July 1826, the fiftieth anniversary of the signing of the Declaration of Independence, leaving behind a lasting political tradition that still influences America and the rest of the world.

Jesus

(c. 6 BCE–c. 30 CE)

RELIGIOUS LEADER AND FOUNDER OF CHRISTIANITY

Jesus, who began his ministry in small towns around Galilee, was a Jew. After the Romans crucified him as rebel, his followers deemed him the Son of God, believing he would soon return to end wickedness in the world and judge the living and the dead. Most Jews rejected this idea, but missionaries made converts among pagans, founding a church that eventually divided into the rival Christian churches of today.

Although Jesus (of Nazareth) is one of the most important historical figures who ever lived, very little historical information is actually known about him. The principal sources for his life and ministry are the four canonical gospels of the Christian Bible: Matthew, Mark, Luke, and John. While these documents contain actual sayings of Jesus, they are products of a developed tradition and themselves use established sources. Alongside information of undoubted historical value, then, there are later stories and sayings inserted for their theological value.

Jesus was born into a milieu of vigorous political activism and religious speculation. Within the context of first-century Judaism, these were interlinked as a result of widespread apocalyptic speculation. In the years when Judaea had been ruled by Hellenistic kings, many of its people began to concentrate their hopes for political change upon a direct intervention by God. The apocalyptic literature, most famously, for example, the Book Of Daniel, that they developed expressed the view that God would act by sending a leader to free the people (“Messiah”) and restore the cult based in the Temple at Jerusalem to its proper function. At the time of Jesus’ birth, the long rule of the region by the Roman client-king Herod the

Great had come to an end. His immediate successors were proving inadequate and so the Romans were undertaking a more direct role in administration and policing.

Jesus came from Nazareth, a village in the hills of Galilee, under the direct authority of one of Herod’s sons, Herod Antipas. Galilee itself was geographically and intellectually peripheral to the Temple cult operating in Jerusalem. Instead, the central religious

institution in Galilean life was the synagogue. The religious community of the synagogue met weekly to be led in formal devotions by a teacher (rabbi). The focus of the synagogue was upon the reading and interpretation of Scripture, and it was in this context that religious reform groups like the Pharisees, who placed particular emphasis upon personal religious devotion, flourished.

Jesus' public ministry, when it began, was mostly amongst the small villages and towns of Galilee. Although there were several cities nearby (Scythopolis [Bet She'an], Tiberias, and Sepphoris [Zippori]—itself only a few kilometers from Nazareth), the gospel accounts make it clear that he preferred to concentrate his activities within the small fishing communities of

the Galilee region, and Capernaum in particular. He seems to have followed on from the earlier ministry of his cousin, John the Baptist. John, an ascetic and itinerant preacher, had demanded a revival of personal piety, to be expressed through a ritual cleansing in water (baptism). At the beginning of his own ministry, Jesus had been baptized by John and, while he did not himself baptize, many of his followers baptized in his name.

Jesus' principal message was an assertion of the need for a personal piety as a response to the love of God. He stressed the need for personal compassion, and many of the miracles associated with him are miracles of healing, which emphasize Jesus' own compassion. In focusing upon personal integrity as

I believe there is no one deeper, lovelier, more sympathetic and more perfect than Jesus—not only is there no one else like him, there never could be anyone like him. • **Fyodor Dostoevsky (1821–1881)**

a measure of piety, Jesus came into conflict with another religious reform movement, the Pharisees, who also laid heavy emphasis upon religious authenticity, although through devoted obedience to Jewish religious law. Jesus' most colorful language was reserved for Pharisees, whom he depicted as liars and hypocrites who were slavishly devoted to the letter of the law.

Jesus' principal notoriety was not so much for his words, however, as for his deeds. He swiftly gained a reputation as a miracle worker through miraculous healings, exorcisms, and even the restoration of life.

When Jesus sought to remove his ministry to Jerusalem, he immediately came into conflict with Temple authorities, whom he accused of profiteering. They in turn sought help from the Roman administrators. Depicting Jesus as a revolutionary and a messianic troublemaker, they secured his conviction and execution by the Romans as a rebel. It is certainly clear that his visit was accompanied by considerable speculation that he would proclaim himself as the Messiah and lead a revolt. While he encouraged this speculation by his entry into Jerusalem in deliberate fulfillment of a messianic prophecy, he stopped short of ever actually claiming to be the Messiah.

Within weeks of his death, a significant number of his followers began to claim that he had risen from the dead. That belief in Jesus' resurrection empowered communities of his followers to survive and grow, forming the kernel of the Christian church. This community expected his imminent return from heaven to complete his messianic task. When that did not occur, Jesus' words and deeds, along with stories about him, were written down as gospels and other documents. Jesus himself wrote nothing except, once when asked to judge a woman caught in adultery, he scribbled some words in the dust (John 8:1–6).

Because of her involvement in conflicts between kings of England and France during the Hundred Years War, which led to her being burnt at the stake as a heretic in 1431, Joan of Arc became a symbol for love of country, feminine independence, and Christian sanctity.

Whether considered as a French national heroine, a prototype of feminism, a political prisoner confronting established institutions, or a saint of the Roman Catholic Church, Joan of Arc is one of the most fascinating and enigmatic women of all time. Considerable controversy surrounds her brief if extraordinary career of one year on the battlefield and one year in prison.

Joan's role in history was shaped by the Hundred Years War (1337–1453), which was essentially a dynastic conflict between the kings of France and England for the control of France. The duke of Burgundy, the most powerful of the French vassals, was allied with England. By the early fifteenth century, large areas of France had been devastated by rapacious mercenary armies employed by the rulers of both countries. In 1428 only central and southern France remained loyal to the Valois king, Charles VII (1422–1461), and the English were besieging Orleans, the key to southern France. It was at this low point in French fortunes that Joan made her appearance.

Joan was born about 1412 in Domremy, on the frontier between Champagne and Lorraine. She referred to herself as Jeanne la Pucelle—"la pucelle" meaning "the maiden" or "the virgin"—out of the pride she took in her virginity. One of the four children of Jacques Darc, a peasant of modest means, she had a normal childhood, although she was unusually

prayerful. At about thirteen, she began to hear voices, which first instructed her to lead a good life and then directed her to obtain Charles VII's coronation in the cathedral of Reims, traditional site of royal coronations, and the expulsion of the English from French soil.

In February 1429, wearing male clothes (she claimed she found them comfortable), Joan visited Charles at his Chinon quarters. After some initial suspicion, Charles agreed to Joan's campaign against the English and supplied her with men, money, male clothing, and a suit of white armor. With an army of about four thousand, Joan began the Orleans campaign on 29 April 1429 and by 8 May 1429 she had succeeded in lifting the siege. Whether this victory actually resulted from her brilliant military strategy and whether it really determined the eventual outcome of the Hundred Years War are debatable questions. What is clear is that Joan restored French morale; her victory was seen as a miracle. By 17 July 1429 she was able to attend Charles's coronation in the cathedral of Reims in a ceremony that gave legitimacy to his kingship. Her fame spread rapidly, not only in France but also in many parts of Europe.

After many victories in the Loire valley, Joan wished to conquer enemy-held Paris. Contrary to the wishes of Charles and his advisers, she attacked Paris in September 1429, but strong resistance forced her to retreat and the king ordered her to abandon the campaign. Thereafter her fortunes declined precipitously. But despite the difficulty of raising money and troops as a freelance general, she continued the assault against the Anglo-Burgundian forces until she was captured at Compiègne by a Burgundian army on 23 May 1430.

Dante Gabriel Rossetti, *Joan of Arc* (1882). This dramatic portrait, found on Rossetti's easel when he died, portrays the heroine with masses of fiery red hair and an opulent robe. Collection of the Fitzwilliam Museum at the University of Cambridge.

The Burgundians sold her to the English, who were convinced that she was a witch. Charles VII made no attempt to rescue her and she was sent to English-held Rouen in Normandy. Between 21 February and 30 May 1431 a tribunal of the Inquisition in Rouen tried her for witchcraft and heresy. Led by Pierre Cauchon, former rector of the University of Paris and the chief judge, the theologians and lawyers who questioned her concentrated on two issues: her claim that she had been guided by the voices of St. Michael, St. Catherine (of Alexandria), and St. Margaret (of Antioch), and her use of male clothing.

The trial judges concluded that she could not have heard voices independently, that is, without the Church Militant, the official church, and that her male clothing symbolized her defiance of the Church. Twelve Articles approved by the University of Paris condemned her as “a liar, an apostate, and a heretic.” On 24 May 1431, exhausted from the long ordeal, Joan signed an abjuration. She promised never to bear arms again, never to use male clothing, and to

renounce her voices. Whether she understood the paper she was signing is arguable. She was then sentenced to life imprisonment.

A few days later Joan resumed wearing male clothes, claiming that her women's clothing had been removed, and stating the God, speaking through her voices, had been saddened by her abjuration. Her conduct and words now made her a relapsed heretic, and she was therefore burnt at the stake on 30 May 1431.

After the Hundred Years War came to an end with France having regained most of its land, Charles asked the Pope, Calixtus III (1455–1458), to authorize a new trial for Joan. The pope agreed, and a nullification trial was held in 1456. The court nullified the verdict of 1431 on the following grounds: judicial procedures had been violated in the previous trial; Joan had been given no facilities to defend herself; and the English had exerted pressure on the court.

Despite the rehabilitation of Joan in 1456, her fame grew slowly, and it was not until the nineteenth century that her image as a national heroine and saint

You, O English, who have no right to this kingdom of France, the King of Heaven orders and commands you through me, Joan the Maid, to leave your fortresses and return to your country, and if you do not so I shall make a [Battle of] Hatay uproar that will be perpetually remembered. • **Joan of Arc (c. 1412–1431)**

took hold on the French mind. She was beatified in 1909 and canonized in 1920. She became a role model for love of country, feminine independence, and Christian sanctity. There are more literary, artistic, dramatic, and musical works on Joan of Arc than on any other woman in history.

Judaism

Judaism's greatest legacy to world history is its success as the earliest entire community to adopt monotheism. The religion's impact on world history is therefore both direct and felt through its relationships with the conquering religious civilizations that followed it, first Christianity and then Islam.

Starting from the Hellenistic period, when outside observers first attempted to write about the “other” in a dispassionate manner, Greek writers observed the unique monotheism of Judaism, noting how this aspect of their religion singled out Jews from all other peoples that the Greeks had encountered. The reports that reached philosophers such as Theophrastus and Megasthenes (c. 300 BCE) led them to consider the Jews a nation of philosophers. The Jews, they wrote, were stubborn believers in a singular god who was both the god of Israel and the god of the world. Other writers noted that the Jews insisted on certain practices that were strange to the Greeks: circumcision, abhorrence at consuming pork, and a kind of insular culture that was at odds with what the Greeks believed to be their own open-mindedness. Such traits were considered by some observers as both peculiar and the reason for what they called—perhaps unconsciously describing their own elitism—Jewish misanthropy, lack of patriotism (toward Greek culture), and general disregard for humankind outside of their own nation.

The Greeks thus articulated both a kind of attraction and repulsion toward Judaism. Despite such ambivalence, however, many Romans (to the dismay of their ruling classes) were fascinated by this religious civilization. Large numbers either converted

or “Judaized,” meaning that they adopted Jewish customs such as holiday observance and food habits without enduring the circumcision that was required for full conversion. Roman writers noted that Judaism's popularity was based on its great antiquity, its written scriptures, its deep sense of morality, and its monotheism. Judaism's engagement with Western civilization was thus deep and enduring but not without controversy.

Judaism had an overwhelming influence on the premodern history of the world west of the Indus River, and an enduring impact on the entire world in the modern period. The impact of Judaism on world history is both direct and felt through its relationships with the conquering religious civilizations that followed, first Christianity and then Islam.

Impact of Origins

Judaism emerged out of a religious civilization based on what is often referred to by scholars as “biblical” or “Israelite” religion. As such, what we today call Judaism must be distinguished from its older forms. In fact, Judaism is only one of the heirs of biblical religion, as are all the faiths in the family of religions referred to as Christianity. Biblical religion itself is multifaceted, since it evolved for centuries during the historical period represented in the Hebrew Bible (Old Testament). It has become evident to scholars that biblical religion was not always purely monotheistic, for it reflects periods of tension between those who would allow rituals associated with figurines representing other powers or deities and those who would accept nothing other than the one god, the God of Israel (1 Sam. 26:19, 1 Kings 11, 2 Kings 23).

An illustration by Jean Fouquet from *Jewish Antiquities*, a manuscript written by Flavius Josephus (38?–100?) that recounts Jewish history from the Creation to the revolt against the Romans in 66 CE. The text was read by early Christians and remained popular with both Christians and Jews. This manuscript, copied and illustrated in the fifteenth century, belonged to French royalty. National Library of France.

It is clear, however, that the people that called itself Israel (the name derives from the biblical figure Jacob, who was also called Israel—Gen. 32:29) was the first community to take on the doctrine of monotheism successfully. It is likely that the concept of monotheism existed among individuals before the emergence of the people of Israel. Even powerful and influential individuals such as the pharaoh Akhenaton (mid-fourteenth century BCE) may have been monotheists or proto-monotheists, but no entire community succeeded in adopting monotheism

prior to ancient Judaism. This is perhaps Judaism's greatest legacy to world history. It established a theological paradigm that would have a profound impact on the nature of all subsequent religions, whether monotheistic or not.

Election

Ancient Israel saw itself as a small and beleaguered monotheistic people living in a world of countless foreign nations, all sharing the temptation of

worshipping multiple deities (Deut. 7:7). Out of this awkward and precarious social and political situation, coupled with a feeling of obvious theological uniqueness, emerged an impression, and then a doctrine, of election, of being chosen by the one and only true god to represent and worship him unreservedly and unconditionally (Deut. 7:6–8). Throughout the Hebrew Bible we find the message that all the nations of the Earth worship their sets of gods, but only Israel worships the One God, the God of the entire world. Election, therefore, became deeply ingrained into the Israelite consciousness. Ironically, despite or perhaps because of Israel's beleaguered position in relation to the mighty idolatrous nations and empires of the ancient world, its unique community commitment to monotheism engendered the feeling that only it was uniquely elected to carry out the will of the true God. Israel was God's royal nation (Exod. 19:5, Deut. 7:6, 14:2, 26:18), and a holy nation (Exod. 19:6, Deut. 14:2, 21). Israel was God's chosen people (Deut. 7:6, Isa. 43:20, 45:4, Pss. 33:12, 132:13, 135:4).

Covenant

The special relationship of election is symbolized by an institution called "covenant" (*b'rit* in Hebrew). The term actually refers to a host of formal or legal relationships in the Hebrew Bible ranging from agreements between two individuals (Gen. 21:22–33, 1 Sam. 18:3) to pacts between nations (1 Kings 5:26, 20:34). But one special type of biblical covenant agreement came to define the relationship between the only community of monotheists and the only true God. Forged between God and Israel, this is the "covenant par excellence," an institution found throughout the Hebrew Bible and a unique contribution of Israelite religion. The covenant was first rendered between God and Abraham's family (Gen. 17). It was reaffirmed with the biblical patriarchs (Gen. 26:23–24, 28:10–15) and then at Mount Sinai (Exod. 19, 24) between God and all the extended families and clans of Israel that were redeemed from Egyptian bondage. This divine covenant was extended also to non-Israelite peoples

who escaped along with Israel in the redemption from Egypt (Exod. 12:38).

The concepts of election and covenantal relationship with God originated with ancient Israel and its religion, but these traits became intimately associated with monotheism in general. Election and covenant, therefore, are not only essential to Judaism, but are intimately associated with Christianity and Islam. Early Christians came to articulate their religion as representing a "new covenant" between God and a "new Israel," namely, those who accept the particular self-definition of Christianity. Christians, therefore, become the new "chosen," with only those who had chosen Christ as savior able to achieve their own salvation (1 Cor. 11:23–32, Heb. 8–9). Although less prominent in Islam, covenant (*'ahd* or *mithaq*) also defines the relationship between God and a newer community of believers. But Islam is less exclusionary in that it accepts, in theory, the salvation of prior communities of righteous believers (Qur'an 2:62, 5:72). Nevertheless, Muslims are defined in the Qur'an as a kind of elect, the most moderate or a "middle community," chosen to be witnesses (Qur'an 2:143), and "the best community brought forth for humankind" (Qur'an 3:110).

Election and covenant, closely associated with Israel and Judaism (and an integral part of all expressions of monotheism), can be viewed as divisive traits. The legacy of Israelite religion is not, however, all exclusion and division. The inclusive and compassionate aspects of the universal religious imperative in Western religions also seem to have originated in ancient Israel.

Compassion For the "Other" and Repairing the World

The exclusivist aspects of monotheism in Israelite religion were always in tension with inclusionism, as defined by care for the stranger and a sense of responsibility toward others. Thus, although Israelites may have considered themselves to be the only people in the ancient world that truly respected the one God of the universe, God was nevertheless the God of all, including those who did not recognize him. Israelite

monotheism thus required care and concern even for those outside of Israel, and this responsibility was articulated through the concept of *imitateo dei*, emulating God, because the creator of all the world must be good: “For the Lord your God is God supreme, who shows no favor and takes no bribe, but upholds the cause of the fatherless and the widow, and befriends the stranger, providing him with food and clothing. You too must befriend the stranger, for you were strangers in the land of Egypt” (Jewish Publication Society, Deut. 10:17–19).

Social Justice

Codes or lists of formalized social precedents (customs) and formulaic duties existed before the emergence of ancient Judaism. These are similar to what today would be called law (obligations to state, society, and private individuals). The ancient Mesopotamian “codes” of Ur-Nammu (twenty-first century BCE), Eshnunna (c. 1800 BCE), and Hammurabi (mid-eighteenth century BCE) existed long before the legal and social requirements enumerated in the biblical parallel, the Book of the Covenant (Exod. 20–23). This pre-Israelite material was as closely associated with a sense of societal justice as that found in the Hebrew Bible. That is, offences would be termed criminal when they were considered inimical to the well-being of society as a whole, and sanctions were imposed by the public authority rather than the injured party or a powerful private individual (the latter might be termed “family justice” and was not law).

On the other hand, the prebiblical codes maintained a sharp tripartite division of society into an upper level of free men, a class of state dependents, and a slave caste. There was no expectation of social mobility between these classes, and the rights, responsibilities, and sanctions in the codes reflected this rigid division. In contrast to the previous systems, the biblical codes extend the rights of the elites to all layers of society: “You shall appoint magistrates and officials for your tribes, in all the settlements that the Lord your God is giving you, and they shall govern the people with due justice. You shall not judge

unfairly: you shall show no partiality; you shall not take bribes, for bribes blind the eyes of the discerning and upset the plea of the just. Justice, justice shall you pursue, that you may thrive and occupy the land that the Lord your God is giving you (Deut. 16:18–20)” and “You shall have one standard for the stranger and citizen alike: for I the Lord am your God” (Lev. 24:22).

Civic Duty and Responsible Behavior

Another of Judaism’s most important legacies, found not only in its sister expressions of monotheism but also in democracies and all forms of responsible government, is the idea that people are responsible to one another. Individuals are accountable, not only for themselves but also for others. This is represented by the term, and the concept, *Torah* (meaning “teaching”), which has sometimes been misunderstood as a rigid code of Israelite law. It should be likened more to a set of behavioral expectations for ritual and social behavior, centered around the idea that the individual is responsible to the group and the group to the individual. That the entire nation is punished by God for the misbehavior of the few is a foundation of Israelite law and referenced throughout the Hebrew Bible. One is accountable for both the behavior and the welfare of one’s fellow. All the people were witnesses at the giving of the Torah at Mount Sinai, and all are therefore responsible to ensure that the Torah teaching is upheld. This is the essence of the Israelite system, which is based upon a balance between individual and community and between freedom and responsibility (Deut. 29–30).

From Israelites to Jews

The true origin of the Israelites remains uncertain. While some have suggested that it lies in Mesopotamia or Egypt, recent scholarship places it within Canaanite society, suggesting that Israel symbolizes a monotheistic trend in Canaanite culture originating perhaps as early as the second millennium BCE that eventuated in an independent identity. The danger of assimilation back into the old and familiar idolatrous

This drawing, which shows the division of Israel among the twelve tribes, is a copy of a work by Rabbi Elijah ben Shlomo Zalman (1720–1797), better known as the Vilna Gaon or Elijah of Vilna (Vilnius, in present-day Lithuania).

ways of local Canaanite culture is a constant theme of biblical literature, and the nations “here at hand” (Deut. 20:15) in the land of Canaan always represent the most dangerous threat to Israel’s distinctive identity and existence.

But the tribes of Israel were not always purely monotheistic, and the journey into the kind of theology we would recognize today as monotheism did not end until the exilic or post-exilic periods after the destruction of the first Temple in Jerusalem in 586 BCE. Prior to that time, such seminal statements as “Who is like you among the gods” (Exod. 15:11) suggest that while ancient Israelite theology required unconditional obedience to the God of Israel, it did not deny the possibility of other gods existing as well. It may have been the realization that the God of Israel could be worshipped even in Babylonian exile that solidified the tendency toward monotheism and convinced the exilic community that there was one God who created the universe, and that the same one God maintained it.

Israel had divided into two separate nations with independent monarchies and centers of worship shortly after the reigns of kings David and Solomon (c. 900 BCE). The northern kingdom, composed of ten of the twelve tribes of Israel, was destroyed by the Assyrian empire in 721 BCE and never recovered. The southern kingdom, formally made up of the

large tribe of Judah and the small tribe of Benjamin (but including parts of other tribes and peoples as well), was destroyed a century and a half later by the Babylonian empire. But the Babylonians were soon overtaken by the Persians, who were friendly to the exiles from the tribal areas of Judah and Benjamin. The Persians invited the exiles to return from their banishment to the east and reestablish themselves in the ancient land. The overwhelming majority of survivors were from the large tribe of Judah, so the returnees joined with those who remained and were soon known as Judeans, or Jews (biblical books of Ezra and Nehemiah), though Jews throughout history have also referred to themselves as Israel, Israelites, or the people or nation of Israel (Hebrew: *b’ney yisra’el* or *‘am yisra’el*).

The Judean community, like its parent, the intertribal community of Israel, remained small in numbers relative to the great empires of Mesopotamia and Egypt. But as a result of the conquests by the Mesopotamian powers and the dispersion of the Israelite tribes, Jewish communities began to establish themselves in many parts of the Mediterranean basin. The largest communities remained in Mesopotamia and Judea, but significant communities grew up also in Egypt, Anatolia, Greece, and North Africa.

These communities did not look like Jewish communities of today, for they practiced a kind of ancient Judaism that was still oriented toward temple worship with sacrifices and burnt offerings. In some places such as Elephantine, an Egyptian island community in the Nile, they established their own temples independent of the Temple in Jerusalem. In others closer in proximity to Jerusalem, the communities joined in the annual pilgrimage festivals to the Jerusalem Temple and worshipped according to the systems described in the Bible.

The Hebrew Bible conveys the message that monotheism always survived precariously and, aside from the Persians, was resented by the nations of the world. The Assyrians, Babylonians, Egyptians, Canaanites, Midianites, and Aramaeans—all opposed the Israelites’ stubborn worship of one god only. The reason for Israel’s isolation in this regard appears quite simple. When traveling, for example, it was a common

Our Jewish experience leads us to be more aware of dangers than of opportunities. This tendency has to be transcended if we are to emerge into a future different from the recent past. • **Abba Eban (1915–2002)**

practice among polytheists to make offerings to the gods of the local area or people. It was considered a common courtesy and expected polite behavior, and to peoples who worshipped multiple deities, it created no theological problem to make a token offering to foreign gods. Not so Israel, which was commanded to worship only the one God of Israel, the God of the universe. The Hebrew Bible indicates that it was quite expected that other peoples worship their national gods or even other people's gods (Judg. 11:23–24), but Israel was allowed to worship only the one God (Jer. 44:1–10).

This situation continued into the Hellenistic period that began with the invasion of Alexander in the 330s BCE, and into the Roman occupation of Judea that began three centuries later. The Judeans remained a small community and largely without power aside from a few generations under the rule of the Jewish Hasmonean dynasty of kings. Finally, in 70 CE, after a major Judean revolt against Roman imperial rule, the Jerusalem Temple was destroyed a second and final time, never to be rebuilt.

By this time, Jews had been dispersed throughout the Mediterranean and Middle Eastern worlds and brought their religion with them. Monotheism, the theological core of ancient Judaism, survived the vicissitudes of history, but the religious rituals and worship that articulated that basic theology evolved and changed over the centuries. The repeated destructions of the Jerusalem Temple put an end to the sacrificial system, but the core idea of a singular god endured. However, the geographical dispersion, influence of multiple cultures, and internal cultural change brought new ideas into biblical Judaism. This eventuated in a synthesis that gave birth to factions or parties, sects, and eventually new religious movements. One of these was the Jesus Movement that began in Judaism and became the starting point out of which the family of Christian religions emerged.

Judaism of the Rabbis

Another was a movement that emerged around a core group of leaders steeped in an oral tradition of Judaism that existed parallel to the sacrificial

system and written scripture of the Bible. Those leaders we know of were almost all men, though it is clear that women were also instrumental in the transmission of oral lore. They could be described as traditionists, and included the Pharisees as well as others. Later, they were known as rabbis. When the long process of recording the oral tradition ended in the sixth century CE, it became known as the Talmud.

This form of Judaism is called Rabbinic Judaism, and all expressions of Judaism today, aside from one tiny group known as Kara'ites, derive from the Judaism of the rabbis and their great source of authority, the Talmud. This Judaism existed in exile for close to two millennia, even in the core land of Judea, which was governed by non-Jews. Rabbinic Judaism always represented the stranger in the lands of others. It is quietist and highly intellectual, relying more on the survivability of its adherents and the wits of its leaders than directly on the biblical God acting in history. Unlike Christianity, Rabbinic Judaism requires little dogmatic theological belief beyond that in the unity of God, and salvation is presumed for all who live a pious life of good deeds.

One of Rabbinic Judaism's great contributions to world history has been its unique ability to adapt to multiple environments within a world hardly tolerant of diversity, religious or otherwise. Its stubborn existence in both Christian and Muslim worlds required all religious leaders, thinkers, and politicians to consider and respond to the Jews, the quintessential "other" in their midst. This required repeated reevaluation of the meaning of self in relation to the other of Judaism, and resulted in the growth of theologies, laws, and various religious and secular sciences in both Jewish and non-Jewish civilizations.

At the same time, the Jews' lack of political power throughout this period required that their religion consider a larger range of possible doctrine than the religions of political powers who could enforce their will by the sword. Judaism therefore contains many ideas but little absolute dogma. The customary argumentation found in Jewish literatures rarely arrives at any final conclusions. Every

Gravestones broken during the Holocaust were set into a wall in the Jewish cemetery in Worms, Germany, where the Jewish community dates back more than a thousand years.

issue and point can and should be revisited and reexamined, and new meanings are always possible. The huge written compendium of the Talmud and its interpretation contain complex discussion and argument over topics that range from folk medicine to legal theory, property law, family law, business ethics, and theologies. The literatures that epitomize Rabbinic Judaism stress the need for a deep and universal intellectual engagement with the divine word in Bible and Talmud, and this foundation of Judaism encouraged a very high per capita involvement in reading and education.

In the Modern World

In the modern period, when Jews were eventually released from their restricted status in the West and were allowed to enter the universities and engage in the professions and sciences, their religious culture provided the intellectual training that would result in contributions far above their per capita

representation. To provide one striking example, Jews make up less than one-hundredth of 1 percent of the world population, yet they account for some 18 percent of the Nobel Prizes awarded in the twentieth century. There is no need to list the many contributions of Jews to the arts, science, literature, and music. Some of the ideas that were incubated in premodern Judaism have come to the fore in contemporary postmodern thought. These include aspects of literary deconstruction and concepts of exile, both of which have had a major impact on current intellectual discourse.

Judaism, like all religions, encompasses more than a theological system of beliefs. It is best described as a religious civilization, and this civilization has had a foundational influence on world civilizations west of the Indus River for two millennia. Its influence comes not only from its own direct contribution, but also through the contribution of the religious civilizations that emerged from or associated themselves with it. Monotheism, the belief in the universality and unity of the divinity, is the very core of Judaism,

and religions that preach monotheistic theologies have not only encompassed the Western and Mediterranean worlds, but now reach deeply beyond into Africa and Eastern Asia. Although representing a tiny fraction of the human population, Jewish religious civilization has remained of great significance in world history.

Justinian I

(483 CE–565 CE)

BYZANTINE ROMAN EMPEROR

As emperor of Rome from 527 to 565 CE, Justinian I engaged the best legal minds to collect all Roman law into a single series of volumes. Justinian's *Codex* replaced all earlier Roman law and was the source of all subsequent Roman law; it remains a key legal text. Justinian sponsored the rebuilding of the Hagia Sophia into the great domed cathedral that survives to this day.

Born Flavius Petrus Sabbatius, Justinian ruled the Roman Empire from 527 until 565 CE. From a Thracian peasant family, he was adopted by Justin, his uncle by marriage, thus taking the name Justinian. Justin, a professional soldier, oversaw the education and promoted the military career of his adopted son. In 518, the elderly emperor Anastasius died without a designated successor and Justin emerged as the successful claimant. Justinian became Justin's principal minister and colleague. It was during this time that Justinian met Theodora, a former actress. Marriages were legally forbidden between men of Justinian's class and women of Theodora's profession, but in 524, Justinian arranged for this law to be changed so that they could marry, and in due course the two wed, commencing a long and extraordinary partnership. In April 527, Justin proclaimed Justinian co-emperor. When Justin died, four months later, Justinian succeeded him without challenge.

Justinian inherited a smoldering conflict with Persia that continued for much of his reign, punctuated only by a brief "Everlasting Peace" signed in 532. The respite this treaty brought nevertheless freed resources for Justinian's great military project: the reconquest of the Western Roman Empire.

He appointed Belisarius, a young and highly gifted general, to this project. In 533, with a small force, Belisarius attacked the Vandal kingdom of Africa. He was swiftly successful and in 535 followed this up with an invasion of Sicily and Ostrogothic Italy. Much of the south fell easily to his forces, although he then had to sustain a counterattack from the Ostrogoths. In 540 he took the Gothic capital of Ravenna, although this did not bring the war to an end. The long conflict was continued by his able successor, the Persarmenian eunuch Narses, who rebuilt a durable imperial presence in Italy.

Both Belisarius and Narses had previously distinguished themselves in a serious disturbance that broke out in Constantinople. One feature of the city's civic life was chariot racing, and there were two particularly prominent chariot-racing teams (or factions): the Blues and Greens. Justinian and Theodora were both known as partisans of the Blues. Early in 532, discontent in Constantinople resulted in violence between the two dominant factions. During the course of a race meeting on 13 January, they suddenly made an alliance, burst out of the Hippodrome, and, chanting the slogan *nika* (conquer), stormed through the city, setting fire to public buildings. For some days, confusion reigned. A reluctant rival to Justinian was proclaimed: Hypatius, nephew of the former emperor Anastasius. Justinian contemplated flight, but the situation was saved by the resolute action of Narses, Belisarius, and others. The Hippodrome was stormed; the rioters were massacred; Hypatius and his brother were executed.

Law was one of Justinian's passions. Once he became emperor, he engaged the empire's best legal

Raphael, *Justinian Presenting the Pandects to Tribonianus* (1511). Fresco. Stanza della Segnatura, Palazzi Pontifici, Vatican.

minds in the collection of all Roman law into a single series of volumes. Justinian's *Codex* replaced all earlier Roman law codes. This was only the beginning. He also set up a commission, under the direction of the quaestor (legal official) Tribonian, to summarize Roman legal authorities in a great reference book (*The Pandects*). The scale of Justinian's legal achievement cannot be overstated. The texts produced through his authority and at his order were the source of all subsequent Roman law, remaining key legal texts to this day.

Justinian sought to interfere directly in the religious controversies of his time. He believed that as emperor he had a divine commission to determine the affairs of the Christian church (caesaropapism). The church itself was bitterly divided in a dispute over the nature

of Christ (the Monophysite controversy). Many in his court, including Theodora, favored the Monophysite view, but Justinian sought to promote a more extreme position (aphthartodocetism).

Justinian was an intelligent and cultured man, an able diplomat, and a good judge of subordinates. A tireless emperor, he sought both to reassert Roman military power and to adorn his empire with great buildings. After the Nika riots, he rebuilt the cathedral church of Hagia Sophia into the great domed structure that survives to this day. He was generous to communities in distress, repairing earthquake damage, and succoring those affected by a major epidemic that raged across the Mediterranean after 541. He outlived most of his subordinates, still troubled by conflict with Persia and his failure to impose a settlement upon the raging religious controversies of the time. At his death in 565, he was succeeded by his nephew Justin II.

Our principal source for Justinian's reign is the prolific writer Procopius, who wrote official literature praising the emperor, as well as a private work (the *Anecdota*) that is critical, even scurrilous. Other sources include the vast legal collection assembled at Justinian's command and the work of the poet Paul the Silentiary.

King Kamehameha of Hawaii was a skilled leader whose military prowess enabled him to defeat his enemies and, by 1810, unify the major islands of Hawaii that were under his control. Also responsive to the needs of the weak and helpless, he enacted various public safety measures for benefit of all.

Arguably the greatest of all indigenous warrior leaders in Fawaiian history, Kamehameha was Hawaii's political bridge to the outside world. He came to power at a time when the islands were still relatively new as a stopover point between the northwest coast of America and its fur trade and the potential riches of Asia via Guangzhou (Canton), China. Domestically, Kamehameha achieved unprecedented success by unifying the major islands under his autocratic control in 1810. Yet as successful as he was, possibly even more notable for that time were the details of how he accomplished what he did. Kamehameha used a wise combination of skills and strategies to both defeat his enemies on the battlefield and thereafter efficiently institute policies to assure peaceful governance. A multifaceted individual, he adhered to the religious system but was also capable of innovating when necessary. He could be as dynamic as any warrior in terms of fighting prowess, but his personal *kapu* (spiritually determined character or destiny) mandated that he also care for the weak and helpless by establishing various edicts to benefit all regarding public safety.

Kamehameha was literally born into greatness, as it is said: a comet blazed across the night sky announcing his birth. Some predicted his would be a life both successful and unprecedented in achievements. So

disturbing were the predictions that the paramount chief of the island of Hawaii ordered the newborn to be put to death, fearing he would one day rise up and usurp the power of the hereditary lineage. Thus Kamehameha was secreted away at birth to be raised out of reach of those who would do him harm. This was a long-standing custom for individuals born of significant chiefly lineage. His formative years were spent training as any young chief would, and eventually his death order was rescinded when it was seen firsthand how very dedicated he was and eager to be of service to his superiors.

The ruler who wanted Kamehameha put to death lost his own life when Kamehameha was a young man. The eventual successor was an uncle of Kamehameha's. As a young man in service to his uncle, Kamehameha was one of the first Hawaiian chiefs to board the ships of James Cook in 1778. The loyal nephew was so able in the performance of his duties, British navigator James Cook mentions Kamehameha by name in his journals as intelligent and inquisitive when reporting the actions of the first party to visit aboard ship. The famed British navigator recognized what an attentive young man Kamehameha was, noting how he took in everything he saw, with his uncle relying on his observations of the foreigners and their ways for much of the visit. When this uncle died, he left control of the island of Hawaii to his son. The war god, though, was placed in the care of Kamehameha, the presumption being if any usurpations of authority were to take place the able young chief would be given every advantage. When the traditional redistribution of land dictated a new balance of power, Kamehameha was shown a total lack of respect given his status in the assembly of Hawaiian nobles. He dedicated the

The statue of Hawaii's first king, Kamehameha I, stands prominently in front of Hawaii's Supreme Court. Library of Congress.

war god and a newly built temple and proceeded to successfully wage battle after battle on the island of Hawaii until he gained complete dominance. Some of the innovations he employed at this time included the placement of heavy artillery on double canoes, use of Western warships, and the largest mobile force of warriors ever organized. Two British subjects in Kamehameha's service were important in his campaigns from the mid-1780s through 1795. John Young and Isaac Davis helped Kamehameha initially in the area of armaments for warfare, modifying traditional fighting forces by teaching some warriors the use of muskets. Cannon that both Young and Davis could operate were mounted on double canoes at the center

deck. They also served as advisers and interpreters regarding foreign ideas, strategies, and influences.

The next objective was to secure the rest of the Hawaiian Islands. He took Maui and its tributaries and then proceeded to Oahu, where his strongest rival was in residence. This opponent was no match for Kamehameha. He was the successor and son of a great Maui warrior, Kahekili, who had taken Oahu in earlier years. The son, however, was not the warrior his father had been. By vanquishing this foe Kamehameha took control of all the islands except Kauai, which was ceded to him in 1810 without major bloodshed.

Kamehameha appointed governors for each of the major islands. He instituted an era of peace that lasted for nearly the entire nineteenth century until the United States violated international law with an initial invasion of the Hawaiian kingdom followed by a military occupation in 1898, further violating Hawaii's neutrality as an independent nation-state. Were it not for Kamehameha I and his dedicated successors, the Hawaiian Islands would surely have fallen under the sway of a major power long before 1898.

Kanem-Bornu

From roughly the eighth to the nineteenth century the Kanem-Bornu state system of northern Africa was strategically located at the crossroads of a trade and cultural network in the Lake Chad basin. As a major center of Islamic learning and scholarship it was instrumental in the spread of Islam to the west, south, and east. Commercially it was a leading source of salt (alum) and slaves to the Mediterranean lands of Christendom.

For a period of nearly a thousand years, Kanem-Bornu was a major political and economic power in northern Africa. Archaeological evidence indicates that its development on the semi-arid plains of the Lake Chad basin occurred in the first half of the first millennium CE among a Kanuri-speaking population of peasant cultivators and livestock herders. Already in the first millennium BCE, the basin was a crossroads for trade and cultural and technological interactions, primarily along a west-east axis, but also along a north-south axis. These networks were factors in the development of the Kanem-Bornu state system.

The earliest known dynasty, the Banu Dugu, or Zaghawa, held sway from the eighth to the late eleventh century, with its capital at Manan. The Saifawa, or Sefuwa, dynasty succeeded it in the second half of the eleventh century and reigned until the mid-nineteenth century. Until the early fourteenth century, Saifawa rule was based in Kanem, northeast of Lake Chad, with its capital at Njimi (from the twelfth to the fourteenth century). In the middle decades of the fourteenth century civil war forced the dynasty to move to the province of Bornu, west of the lake, where a new capital, Ngazargamu, was created.

The Kanem State

With a royal ideology of divine kingship, the Banu Dugu dynasty of the eighth and ninth centuries ruled a rural population of peasants and herders and an urban population of traders and artisans. In this period the growth of a long-distance trade in salt and slaves, wars of expansion toward the Nile Valley and into the southern Sahara, and the arrival from North Africa of merchants and clerics of the Ibadi branch of the Kharijites marked its history. Merchants and some of the Kanem elite converted to Ibadi Islam in the ninth and tenth centuries. Surplus from the countryside and tribute from the large, salt-producing oasis of Kawar to the north were principal sources of revenue.

Rise of the Saifawa Dynasty

A commercial economic system (a salt-slave circuit) extended from the plains east of Lake Chad to the Tibesti Mountains in the central Sahara, via the Kawar oasis, to Zawila, a principal trading center in the northern Saharan oasis known as the Fezzan (in present-day Libya). In the course of the tenth and eleventh centuries an expanding trans-savanna gold trade route that ran from the Middle Niger Valley eastward to the port of Zeila in the Horn of Africa and the port of Aden on the southern Arabian Peninsula passed through Kanem. The relative decline of the salt-slave circuit and the expansion of the trans-savanna gold trade contributed to the fall of the Banu Dugu dynasty and the rise of the Saifawa. The rural-based Banu Dagu lost the support of the Kanem merchant class, which shifted its allegiance to the urban-based Saifawa, a distant branch of the royal dynasty. This

A caravan approaches Kanem-Bornu, circa 1700, a time of political consolidation, prosperity, population growth, and peace.

class and its North African associates became less interested in salt and slaves and more interested in a share of the growing gold trade, which extended to the Nile Valley (Egypt and Nubia) and the Indian Ocean trading system.

The new dynasty established a different stream of Islam, Sunni Maliki Islam, as the state religion, but it was not until the thirteenth century that the religion spread among the general population. A number of Kanemi sultans went on pilgrimage to Mecca. Mosques were built, schools were set up, clerics were brought into the state organization, and autonomous clerical communities were founded. Sultan al-hajj Dunama Dibalami (reigned 1210–1248) performed the pilgrimage and in 1242 established a hostel in Cairo for other pilgrims and students from Kanem. From the twelfth to the fourteenth century, Kanemi sultans conducted military campaigns in all directions, especially toward Hausaland in the west, the Fezzan, and the Nile Valley. Newly conquered lands were granted as fiefs to military commanders. At the heart of the political system was a confederacy of aristocratic clans linked to the ruling dynasty. Senior office holders were drawn from the ranks of the great fief holders, the royal princes and princesses, and Muslim clerics and officers. Local functionaries and tributary rulers occupied the lower ranks of the political system. Imperial expansion enabled the capital and the Kanem heartland to flourish and to achieve recognition beyond the Islamic world. Among medieval European cartographers, Kanem was known under the names Occitan and Organa.

The Karimi Merchants

Kanem's role in international trade can be gleaned from the activities of the wealthy and influential Karimi (or Karim) merchants, who were the preeminent traders in the Islamic world from the twelfth to the fifteenth century. Some scholars believe that the term *Karimi* derives from Kanem, the merchants' place of origin, and that they rose to prominence in Kanem in the period from 950 to 1050 and in Egypt and Aden in the eleventh century. By the thirteenth century they all but monopolized the trade with Byzantium, the Middle East, India, Southeast Asia, and China as well as the Red Sea ports, and their commercial activities carried them to Ethiopia, Nubia (present-day northern Sudan and southern Egypt), and Mali and Ghana (Wagadu) in West Africa. Among the wealthiest merchant groups in the Islamic world, they maintained a profitable and vibrant commercial traffic between Asia and Africa.

The revolts and civil wars that plagued fourteenth-century Kanem had several causes, including ambitious estate holders' desire for autonomy, rival and aspiring claimants to the kingship, and a discontented and rebellious peasantry. Njimi was destroyed, probably toward the end of the century, and the Saifawa were forced out of Kanem.

The Bornu State

The founding, in about 1480, of a new Saifawa capital, Ngazargamu, by Sultan Ali ibn Dunama (reigned 1470–1503) signaled a new chapter in the imperial history of the Lake Chad basin. During the sultan's pilgrimage to Mecca in about 1484, a claimant to the throne of the Islamic Abbasid dynasty (749/750–1258) invested him as the caliph of Takrur (that is, Islamic West Africa). From this time onward, Bornu rulers regarded themselves as caliphs, a claim that was widely accepted. Ali ibn Dunama and his successors ended the civil wars, reconquered Kanem, and launched military conquests across vast territories, such that in the seventeenth and eighteenth centuries Bornu was one of the largest states in Africa. It

dominated Hausaland, the trade routes leading to Tripoli on the North African coast, and the sultanates up to the Nile Valley.

The seventeenth and eighteenth centuries were times of political consolidation, economic expansion and prosperity, population growth, and peace. Towns and villages increased in number, as a result, for example, of the spread of clerical communities. Local trade, based on geographical specializations within a regional economy, expanded substantially. Bornu merchant caravans transported a wide variety of goods to and from distant markets—the Nile Valley, the Middle East, North Africa, and many parts of West Africa.

Bornu Innovations

The Bornu caliphate differed significantly from the Kanem sultanate. In Kanem there was a close association between the state and religious learning, while in Bornu there was a close association between trade and religious learning. In Kanem the sultan ruled as the first among the great landed elite. In Bornu the caliph headed a centralized bureaucracy consisting of slaves, including eunuchs, and persons of servile descent. Bornu was divided into landed estates (or fiefs) held by the new slave aristocracy (slaves to the

ruling sovereign), courtiers or servants of the king, and military commanders. Unlike their Kanem predecessors, all of the senior officials lived in the capital and not on their estates. They toured their districts only to collect taxes and during times of unrest. In contrast to the old aristocracy, the new ruling class was entirely Muslim. The traditional estate holders and aristocratic clans had titles but little or no power. Rulers relied on slave troops and mercenaries and were thus militarily independent of village communities. Islamic law replaced customary law, the ruler appointed Muslim judges throughout the land, mosques were built in the rural areas, and a hostel was founded in Mecca for Bornu pilgrims.

There were numerous units within the state that were not included in the dominant administrative structure. Semiautonomous territories, clerical towns, social-occupational groups (such as camel and cattle pastoralists), and families in possession of rights of privilege were directly responsible to the ruler and not to any fief holder. This political arrangement reflected old traditions and practices from Kanem.

In 1808 the capital Ngazagamu was sacked by followers of Uthman dan Fodio (1754–1817) and in 1812 completely abandoned. Several western provinces were occupied and permanently lost. A religious movement (1804–1810) in Hausaland—the jihad of Uthman dan Fodio—resulted in a new political order, the Sokoto caliphate, which successfully challenged the dominance of Bornu and the authority of the Saifawa. Bornu entered a period of decline, and the prestige and power of the Saifawa dynasty waned.

The al-Kanemi Dynasty

To meet the military and political threats of the jihad and Sokoto, Caliph Dunama Lefami (reigned 1808–1817) called upon the influential scholar Shaykh al-hajj Muhammad al-Amin al-Kanemi (d. 1837) to defend Bornu and the Saifawa. Al-Kanemi, who was to found a new dynasty, defeated the jihad forces, and for this and other services he was appointed a semi-autonomous official and was awarded two enormous fiefs. The latter became his power base. By absorbing

semiautonomous territories and communities and frontier territories and by maintaining a standing army, he was able to achieve military and political preeminence. In 1814 he founded Kukuwa as his capital. He became the de facto ruler of Bornu, with the caliph having power only over the royal court. Shaykh 'Umar al-Kanemi (reigned 1837–1881), al-Kanemi's son and successor, ended the reign of the Saifawa in 1846.

The administrative structure of Bornu under the al-Kanemi dynasty combined features associated with the Saifawa period with innovations that Muhammad al-Kanemi developed. Among his reforms were the reorganization of the Bornu Council of State and the creation of a standing royal slave army. The slave component in the administration was more powerful than under the Saifawa, but advancement within the political system for both free and slave was through clientage within a hierarchy of patron-client relations headed by the Shaykh. The entire state revenue was recognized as the Shaykh's personal property, which he could dispose of at will. Bornu's role as a major trade center declined after the mid-nineteenth century. It was increasingly drawn into the more dynamic economy of the Sokoto caliphate as a supplier of raw materials and a consumer of luxuries.

The rule of the al-Kanemi dynasty ended in 1893 when Rabih Zubeir (d. 1900), coming from the Nile Valley, invaded and defeated an internally divided Bornu. Kukuwa was sacked and Rabih established himself in Dikwa, his new capital, as the sovereign of Bornu. However, his rule was cut short in 1900 by advancing European armies, which colonized the area.

Regional and Supraregional Impact

Throughout much of its history Kanem-Bornu, centrally located at the Chad basin crossroads, was economically and politically oriented to the Sahara to the north and the Nile Valley to the east. When this orientation was effectively blocked in the second half of the nineteenth century, the society experienced severe internal divisions and fell into inevitable decline.

The historical significance of Kanem-Bornu can be understood in terms of its regional and supraregional significance. At both a regional and supraregional level it was instrumental in the spread of Islam over an extensive territory westward to Hausaland, southward to the lands below the Lake Chad basin, and eastward to the lands between Lake Chad and the Middle Nile Valley. Regionally, it was a major center of Islamic learning and scholarship. The political institutions of the principal polities in this vast region, as well as the confederations and town governments in the central and eastern Sahara, derive in large part from Kanem-Bornu and in near and distant lands state-building strategies followed Kanem-Bornu examples.

Commercially, Kanem-Bornu was equally significant. It was a leading source of salt (alum) and slaves to the Mediterranean lands of Christendom and Islam. Salt/alum was an essential ingredient needed by textile producers in the West and in Egypt and North Africa. Kanem-Bornu was also indispensable to the development of royal military forces in North Africa polities where the main military units depended upon (adult male) slave imports from Kanem-Bornu. These units were employed in invasions of southern Europe and wars against the Crusaders. In addition, the Karami merchants who have been linked with Kanem were specialists in the Indian Ocean trade and established the traffic in gold and other goods between Asia and Africa.

Kangxi Emperor

(1654–1722)

SECOND EMPEROR OF CHINA'S QING DYNASTY

During Emperor Kangxi's sixty-year reign, the borders of the Qing dynasty (1644–1911/12) were strengthened, Manchu rule in China was solidified, and China's economy, culture, and population prospered.

The sixty-year reign of Kangxi, from 1662 to 1722, was one of the longest and most successful in Chinese history. Along with solidifying Manchu rule in China and countering Russian and Mongol threats along the empire's borders, Kangxi also proved himself to be a cultured and able administrator who skillfully bridged the divide between his nomadic Manchu heritage and the agrarian civilization of his Han Chinese subjects.

In the winter of 1661 Emperor Shunzhi, the first emperor of the Qing dynasty (1644–1911/12), contracted smallpox, and on his deathbed he named his third son, Xuan Ye, his heir, possibly because the youth had survived a battle with the disease that shortly was to claim his father, and it was believed that this was a sign that the child would have a long life. Twelve days after his father's death, Xuan Ye was proclaimed emperor and took the reign name Kangxi. As the young emperor was only seven years old, a council of four regents was appointed to rule while the child was in his minority. After an abortive first attempt to assert his authority, Kangxi managed at age fifteen, with the help of his mother's uncle and a group of loyal Manchu officers, to take control of the empire, thus beginning a reign that would last for the next six decades and make him one of the most respected rulers in all of Chinese history.

One of the greatest problems facing the young emperor was the need to unify all of the empire under

Manchu rule. To this end, Kangxi ordered that a military campaign be conducted against the three Chinese generals who had directed the conquest of south and southwest China in the 1650s. These generals, Shang Kexi, Geng Jimao, and Wu Sangui, had earlier been named princes and had their sons married to the daughters of Manchu nobles as recognition of their loyalty to the Qing cause. By the early 1670s, however, Kangxi desired to remove these generals, who were referred to as the "Three Feudatories" due to the high degree of independence they wielded over southern China. The campaign against these former allies was bitter and bloody, but after eight years of fighting Kangxi subdued the last of the Chinese resistance in the south. The emperor then turned his attention to conquering the island of Taiwan, where a large army under the command of the Zheng family had established itself in 1659. A fleet of three hundred ships, under the command of Admiral Shi Lang, whose father and brothers had been killed in the 1650s by the rebel leader Zheng Chenggong (Koxinga), was assembled to capture the island. In the summer of 1683, Admiral Shi's fleet dealt the rebels a fatal blow off the coast of Taiwan and the last remnants of Chinese resistance surrendered.

Kangxi also worked to protect his empire's northern and western borders against foreign threats. By the late seventeenth century, the Russians had conquered most of Siberia and were exerting pressure along the Amur River in northern Manchuria. Kangxi attempted to remove this threat by laying siege to the Russian military presence at Fort Albazin in the mid 1680s. In 1689, with the assistance of Jesuit missionaries who served as translators, representatives of the Qing and Russian empires met at the town of

Emperor Kangxi, renowned as a cultured and able administrator, poses in court dress. This portrait hangs at the Palace Museum, Beijing.

Nerchinsk and signed a peace treaty, the first diplomatic treaty between China and a European nation. In the years that followed, Russian embassies travelled to the Qing court at Beijing and the two nations enjoyed cordial commercial and diplomatic relations.

The emperor Kangxi had been anxious to solve his problems with Russia in order to focus his efforts on the greater threat posed by the Eleuth king Galdan in western Mongolia. In 1699 Galdan's armies invaded the territory of the Khalkhas, a nomadic people who lived in eastern Mongolia. The Khalkhas sought refuge in Inner Mongolia, and in 1691 their princes pledged alliance to Kangxi and accepted Qing suzerainty. Five years later Galdan's armies again invaded Khalkha

territory, and this time Kangxi himself headed an expedition to end this threat along his northern frontier. In 1697 Galdan's forces were defeated and the Eleuth king was forced to commit suicide. The northern border of the Qing Empire was now stabilized, and all of the peoples of Outer Mongolia were placed firmly under Manchu control. In 1720, Qing armies also established control over Tibet.

Domestically Kangxi proved to be a conscientious ruler, and under his administration the empire prospered. He insured that public works, such as maintenance of the dikes along the Huang (Yellow) River and the navigability of the Grand Canal, were completed. He personally conducted six tours of the empire during his reign, during which he inspected conservancy projects and the work of his officials. While in Beijing he continued to keep a close watch on the work of the empire's bureaucracy by reading secret reports compiled by teams of censors who were routinely sent to inspect the work of the officialdom. Having mastered classical Chinese, Kangxi was a great patron of Chinese culture and scholarship, and during his rule he sponsored court painters, academies of learning, imperial porcelain factories, and the compilation of works of literature and philosophy. In an effort to retain the traditions of his nomadic heritage, Kangxi also enjoyed periodic hunting trips with members of the Manchu aristocracy.

Emperor Kangxi was a ruler who exhibited great intellectual curiosity, and this was demonstrated by his use of Jesuit advisers. Not only were the missionaries used as translators during the negotiations with the Russians at Nerchinsk, but they were also employed as cartographers and charged with running the Imperial Board of Astronomy because of their demonstrated mathematical knowledge and ability to correct the Chinese calendar.

Kangxi had twenty sons and eight daughters who lived to adult age, but only one of these, the prince Yinreng, was born to the first empress. The young prince was named heir apparent at a young age and was left to serve as acting ruler when his father was absent from the capital during the military campaign against Galdan and the inspection tours of

If you want children to keep their feet on the ground, put some responsibility on their shoulders. • **Abigail Van Buren, nee Pauline Esther Friedman (1918–2002)**

the south. Yinren, however, proved to have a cruel personality, and after years of reading secret reports and memorials documenting the prince's abusive behavior, Kangxi finally revoked Yinren's status as heir-apparent in 1708 and ordered him arrested. When Kangxi died in December 1722 he had failed to fulfill an important responsibility by not publicly naming an heir, and, in the power struggle that followed his death, his fourth son took the throne under the reign name Yongzheng. Despite his failure to name an heir, Kangxi is recognized, along with Qianlong (reigned 1736–1799), as one of two greatest emperors of the Qing period. The empire's borders were strengthened through his military campaigns, and China's economy, culture and population prospered due to the new stability.

Kenyatta, Jomo

(1891?–1978)

FIRST PRIME MINISTER AND PRESIDENT OF INDEPENDENT KENYA

Jomo Kenyatta became the first president of the Republic of Kenya in 1962. He is important in word history for his campaign against neocolonialism. Unlike more socialist-inclined African leaders, he advocated pro-Western policies of economic development, but he became a role model of younger African leaders for asserting the rights of African countries in the modern world.

Born in the Kikuyu highlands of East Africa, Jomo Kenyatta rose to become an international spokesman for African nationalism and an elder statesman for the moderate wing of the nonaligned movement of developing nations that wanted to avoid placing themselves in either the U.S.-led or the Soviet-led camps during the Cold War. As a boy he received a traditional Kikuyu education, moving through childhood with other members of his age group and thereby finding his place in Kikuyu society. About 1909 he joined the Church of Scotland and attended a mission elementary school; he was baptized John Peter Kamau in 1914. Employed by a government contractor, he was exempted from otherwise compulsory military labor service during World War I. Later, as Johnstone Kenyatta, he worked for the Nairobi municipal authority; in Nairobi he joined the East Africa Association of similarly educated Africans and then in 1924 the newly formed Kikuyu Central Association (KCA). He was soon editing the Association's publication *Muigwithania* ("Reconciler" in Kikuyu), which attracted the attention of British colonial authorities since it was the territory's first vernacular publication and actively opposed land alienation (policies by which British interests disposed Kenyans off

their land in favor of colonial settlers). Kenyatta was elected general secretary of the KCA in 1928, and the following year he represented the Association's views before the British Colonial Office in London.

In 1931 he returned to Kenya to give evidence before the Kenya Land Commission on the matter of Kikuyu land alienation, but he was back in England the next year studying at Selly Oak College in Birmingham. He also traveled widely in Europe, attending several conferences of African and other colonial peoples sponsored by progressive and socialist agencies, and he spent a year at the Comintern Institute in Moscow. He later studied anthropology with the famous anthropologist Bronislaw Malinowski (1884–1942) at the London School of Economics, completing his book *Facing Mount Kenya*, an extraordinary account of a way of life that was also a plea for its preservation. Thereafter he was known as Jomo Kenyatta.

Kenyatta brought those same concerns to the 1948 Pan Africa Congress in Manchester, England, for which he served on the organizing committee as assistant secretary. He joined Kwame Nkrumah (the future prime minister of independent Ghana), Hastings Banda (the future president of independent Malawi), and other African delegates in calling for an end to the colonialism that still dominated their continent. The conference, along with other gatherings of Africans in London, created the intellectual environment that later manifested itself in the Organization of African Unity. Kenyatta returned to British East Africa in 1946 and the next year became president of the Kenya Africa Union (KAU), which had been formed in 1944 as a primarily Kikuyu cultural association. As president of the KAU, Kenyatta supported calls for the preservation of Kikuyu ways in the face of

Our children may learn about the heroes of the past. Our task is to make ourselves the architects of the future. • **Jomo Kenyatta (1894–1978)**

continued British domination of the economic and political life of his country, but as the only African political leader in Kenya capable of uniting Africans throughout the territory, Kenyatta worked steadfastly to broaden the base of the KAU into a national movement. He accomplished this by specifically including other groups, such as the Kamba and Meru, in its anticolonial activities.

Despite these public stands, he was unsuccessful in tempering the most militant Kikuyu protests, which gave rise to the Mau Mau guerrilla movement. After a number of incidents—in which, ironically, more Africans accused of collaboration were killed than Europeans—the British declared a state of emergency, increased their police and military presence, banned the KAU, and arrested Kenyatta and other leaders of the association. Kenyatta was accused of being the mastermind of the Mau Mau movement, and in 1952 he and other KAU officials were tried. Despite continuing denials of his involvement, and based on likely perjured testimony, Kenyatta was convicted and imprisoned for a term of seven years.

The British military continued to campaign against the Mau Mau insurgents, finally gaining the upper hand in 1959, when the state of emergency was lifted. The next year a new political party, the Kenya African National Union (KANU), proclaimed Kenyatta its president and campaigned for his release from prison, which came in 1961. But colonial leaders insisted that Kenyatta should not hold public office, so when KANU won a majority of seats in elections for internal self-government in 1962, the party refused to form a government. Only after a second electoral victory in 1962 was Kenyatta permitted to assume the position of prime minister. He continued in that position upon Kenya's independence in 1963, and in

the following year he became the first president of the Republic of Kenya.

Under his leadership Kenya worked to follow his personal slogan, “Harambee” (meaning “let’s all pull together” in Swahili), with policies that invited British settlers and their descendents to be full citizens of the country.

On the international scene, Kenyatta drew much attention as an elder statesman for the nonaligned movement, in particular in its campaign against what he and others described as neocolonialism. But he also advocated pro-Western policies of economic development, a stance that sometimes separated him from other, more socialist-inclined, African leaders. Nonetheless, his long insistence on the viability of African societies and steadfast assertion of their rights in the modern world continued to impress younger African leaders as a model assertive leadership. He died in 1978 while still president of Kenya.

Khmer Kingdom

The Khmer acquired and maintained their substantial kingdom by a skillful combination of warfare, diplomacy, and pragmatism. At its height in the twelfth and thirteenth centuries, the Khmer-established Angkor Empire controlled much of present-day Cambodia, Laos, Thailand, and southern Vietnam. After 1431, the Khmer became pawns perched uneasily between the expanding Vietnamese and Thai states.

The Khmer people established some of the earliest Southeast Asian states as well as the great Angkor Empire. Angkor dominated much of mainland Southeast Asia for half a millennium beginning in the ninth century, flourishing as one of Eurasia's most creative societies.

Early Khmer States and Indian Influences

Just prior to the common era India began exercising a strong influence in Southeast Asia. The process by which Indian ideas spread into and influenced many Southeast Asians, often termed "Indianization," mixed Indian ideas with local ideas. This occurred at about the same time as classical Greco-Roman civilization was spreading around the Mediterranean. Indian traders and priests began regularly traveling the oceanic trade routes to mainland Southeast Asia, which they termed the "land of gold," settling in some of the states and marrying into or becoming advisers to influential families. They brought with them Indian concepts of religion, government, and the arts, as well as writing systems. Mahayana Buddhism and

Hinduism became important in the region, especially among the upper classes.

The first great Khmer state, Funan, thrived from around 60 to 540 CE. Centered in the fertile Mekong River delta of southern Vietnam, Funan was in regular contact with China, had adopted many Indian practices, valued literacy, and built masterful canal systems linking its major cities. At times Funan may have dominated much of what is today Cambodia and southern Thailand. With its access to major land and sea trade routes, Funan was part of large trading networks. Trade goods from as far as Rome, Arabia, Central Asia, and perhaps East Africa have been found in its ruins. Merchants from various countries, including India and China, lived in the major port city, exporting forest products such as ivory, rhinoceros horn, and wild spices. Another Khmer kingdom or grouping of city-states, called by the Chinese Zhenla, emerged inland in the Mekong River basin around the fifth century and gradually outshone Funan. Zhenla played a dominant regional role until the seventh century, when it was destroyed by a civil war.

The Angkor Empire and Government

The greatest Khmer state was the Indianized kingdom of Angkor, established by a visionary king, Jayavarman II (c. 770–850; reigned c. 790–850), in 802. The name *Angkor* derives from the Sanskrit term for holy city, and Jayavarman identified himself with the Hindu god Siva. Hindu priests probably brought the Indian idea of god kings to Khmer rulers. His successors extended and consolidated the kingdom. At its

height in the twelfth and thirteenth centuries Angkor had a loosely integrated empire controlling much of present day Cambodia, Laos, Thailand, and southern Vietnam. The Khmer acquired and maintained their substantial empire by a skillful combination of warfare, diplomacy, and pragmatism.

This vigorous imperial system compares favorably with the fragmented states of medieval Europe, bearing some resemblance to the Carolingian state founded by Charlemagne in northwestern Europe around the same time. The well-financed Angkor government supported substantial public services, including a system of hospitals, schools, and libraries. Some kings were noted as avid patrons of the arts. Theater, art, and dance reflected Hindu values. For example, at festivals troupes of dancers enacted scenes from Hindu holy books.

Monuments, Canals, and Urbanization

Many magnificent stone temple mountains were built as sanctuaries and mausoleums, designed to represent the Hindu conception of the cosmos. These temples also provided vivid and concrete symbols of a monarch's earthly power, since the construction involved advanced engineering skills and massive amounts of drafted labor. The most famous temple complex is

Angkor Wat, the largest religious building in the pre-modern world. It dwarfed the magnificent cathedrals of Europe and grand mosques of Baghdad or Cairo. The reliefs carved into stone at Angkor Wat and other temples provide glimpses of daily life, showing fishing boats, midwives attending a childbirth, merchant stalls, jugglers and dancers at a festival, peasants bringing goods to market, the crowd at a cockfight, and men playing chess.

Drafted workers also constructed an extensive hydraulic network of canals and reservoirs for efficient water distribution, demonstrating some of the most advanced civil engineering in the premodern world. The Khmer were successful farmers, obtaining astonishing productivity from what was originally only a moderately fertile region. The Khmer may have had the most productive agriculture in premodern history, producing three to four crops a year. Only a few pre-modern peoples could match Khmer farming capabilities, which depended on an ingenious water storage system and the unusual geography of central Cambodia, including a large seasonal lake which renewed the soil. But historians still debate whether Angkor wet-rice farming was based chiefly on rainfall and flooding or irrigation, or perhaps a combination of both.

By the twelfth century the bustling capital city, Angkor Thom, and its immediate environs had a substantial population, perhaps as many as one million people, much larger than any medieval European city and comparable to all but the largest Chinese and Arab cities of that era. The magnificent temples still standing today and the remnants of the remarkable water control network testify to the prosperity and organization of the society. While the source of some speculation, the evidence is unclear whether neighboring or subsequent states imitated or adapted the Khmer water control network.

Angkor Society

The rigid Khmer social structure resembled that of medieval Europe in some respects. Each class had its appointed role, bound by many rules. Priestly families led a cult for the popular worship of the kings,

who claimed godlike powers. Below the priests were the trade guilds. The vast majority of people were essentially serfs tied to the soil they plowed, to the temples they served, and to the king's army. In exchange for considerable material security, Khmer commoners tolerated a highly unequal distribution of wealth as well as substantial labor demands. No India-style caste system existed despite the strong Hindu influence. Like many premodern societies, there were many slaves and people in some form of temporary or permanent involuntary servitude.

Khmer women played a much more important role in society and politics than in most other places in the world at that time, due in part to a matrilineal tradition. Women dominated the palace staff, and some were even gladiators and warriors. They also operated most of the retail stalls. Chinese visitors were shocked at their liberated behavior. Women were also active in philanthropy, scholarship, and the arts, including the national passion for poetry. Unfortunately all the manuscripts, written on palm leaves, deteriorated over the centuries.

The Heritage of Angkor

Eventually Angkor declined from varied causes. Military expansion overstretched resources. Increased temple building resulted in higher tax levies and forced labor, antagonizing much of the population into rebellion. There is some evidence that there may have been a breakdown of the irrigation system. Outside forces also played a role. Amidst the growing disruption, Theravada Buddhism spread into Angkor in the mid-thirteenth century from Sri Lanka, and gradually became the dominant religion, promoting nonviolence and undermining god-kings. By the thirteenth century the ancestors of the Thai and Lao peoples had migrated from southwest China and set up states in northern Thailand and the Mekong River valley. They repeatedly sacked Angkor and seized much of the empire's territory. The Angkor capital was abandoned in 1431, and the imperial structure disintegrated by 1440. But Angkor left an enduring legacy as the Thai

peoples gradually adopted many aspects of Khmer government, culture, and religion.

The ensuing centuries proved difficult. The Khmer became pawns perched uneasily between the expanding Vietnamese and Thai states. Both their neighbors periodically attempted, often successfully, to control or dominate the demoralized remnants of the once splendid Angkor civilization. Beginning in 1863 the French controlled Cambodia, a colonization that only ended in 1953. Terrible conflict and genocide devastated Cambodia from 1970 until the mid-1990s. Yet, even today, the image and spirit of long abandoned Angkor continues to inspire the Khmer people.

King, Martin Luther, Jr.

(1929–1968)

U.S. CIVIL RIGHTS LEADER

Martin Luther King Jr.'s leadership, from the mid-1950s until his death in 1968, was critical to the civil rights movement's success in ending the legal segregation of African Americans in the South and other parts of the United States.

As one of the most prominent civil rights leaders of the mid-twentieth-century United States, Martin Luther King Jr. used nonviolent tactics borrowed from Mohandas Gandhi in seeking to overturn segregation, a decision that contributed to King's earning the Nobel Peace Prize in 1964.

King (original name Michael Luther King Jr.) was the son and maternal grandson of Baptist preachers, both of whom served at the prestigious Ebenezer Baptist Church in Atlanta, Georgia. His parents' comfortable middle-class lifestyle afforded young Martin a solid education and opportunities not available to all black Americans at the height of segregation. His secure upbringing, however, did not shield him from the prejudices then common throughout the South.

King entered Morehouse College at age fifteen under a special wartime program intended to boost enrollment. He graduated in 1948 after entering the ministry, and he spent the next three years at Crozier Theological Seminary in Chester, Pennsylvania, where he studied Gandhi's philosophy of nonviolence as well as the works of contemporary Protestant theologians. After earning a bachelor of divinity degree, King moved on to Boston University to earn a doctorate. There he met Coretta Scott, a native Alabamian who was studying at the New England Conservatory of Music. They were married in 1953 and had four children. King received his doctoral degree in

1955, a year after he accepted a position as pastor of the Dexter Avenue Baptist Church in Montgomery, Alabama.

Montgomery's civil rights advocates decided in 1955 to contest racial segregation on that city's public transportation system. When Rosa Parks, an African-American woman, refused to give up her bus seat to a white passenger and police arrested her for violating the city's segregation law, the activists formed the Montgomery Improvement Association to boycott the transportation system. They chose King as their leader. He quickly showed his commitment to the cause through his inspiring rhetoric and public fearlessness after his family home had been bombed. Just over one year after the start of the boycott, the city integrated the bus system.

Wanting to capitalize on the success of the Montgomery boycott, King organized the Southern Christian Leadership Conference (SCLC) in hopes of creating a national movement. He lectured on race-related issues around the country and abroad. A meeting with Indian Prime Minister Jawaharlal Nehru helped cement his belief in using nonviolent resistance. He also drew inspiration from the struggles of Africans trying to overthrow colonialism and establish independent nations.

In 1960, King became co-pastor at Ebenezer Baptist Church with his father. The position allowed him to devote much of his time to the SCLC and civil rights. Sensing the time had come to launch a concentrated attack against segregation, he supported sit-in demonstrations staged by local black college students. His arrest and imprisonment for violating his probation on a minor traffic offense received national attention, especially after Democratic presidential

Martin Luther King Jr. at a press conference. Photo by Marion S. Tricosko. Library of Congress.

candidate John F. Kennedy interceded on his behalf. The move garnered so much publicity that it most likely contributed to Kennedy's narrow victory eight days later.

The next five years found King's influence at its peak. He did not shy away from using the news media—especially television, then in its infancy—to bring national and international attention to the civil rights struggle. Images of women and children offering no resistance while being beaten by police or attacked by police dogs stunned the American public, and brought pressure on the administrations of Kennedy and Lyndon B. Johnson to enact and enforce federal civil rights legislation.

Not everyone in the black community supported King's tactics. In the spring of 1963, he wrote his famous "Letter from Birmingham Jail" defending the use of nonviolent tactics instead of the simple negotiation supported by many black clergy of Birmingham. King argued that nonviolent direct action

would bring about such a crisis that the white community would have no choice but to negotiate. Later that summer, to bring about further pressure on federal legislators, King participated in the historic March on Washington. Nearly 200,000 attended the peaceful rally to demand equal justice under the law. There, he gave his famous "I Have a Dream" speech, in which he emphasized his belief that one day, all men would be brothers, regardless of racial or cultural distinctions. The following year saw the passage of the Civil Rights Act of 1964, authorizing the federal government to desegregate public accommodations and outlawing discrimination in publicly owned facilities and in employment. The high watermark of the civil rights movement, and perhaps of King's life, came in December when he received the Nobel Prize for Peace.

The Selma, Alabama, demonstrations of March 1965 revealed the first opposition to King's tactics within the civil rights movement. When King opted not to confront armed state troopers and instead turn back, the decision cost him the support of many young radicals who were already criticizing him for being too cautious. Though the march influenced the passage of the Voting Rights Act of 1965, King appeared to be growing out of touch with radical activists who faced poverty and other problems in addition to segregation in urban centers and the North. Their public derision of King and the seeming failure of nonviolent demonstrations to bring about further change led him to change his focus and move beyond concerns of race. In 1967, he firmly came out in opposition to the Vietnam War, a decision that cost him further support in parts of the black community and in Washington. His attempt to widen his base by organizing a coalition of the poor of all races did not gain him great support in any segment of the population.

Undeterred, King began planning a Poor People's March to Washington in the spring of 1968. He interrupted his planning efforts to go to Memphis, Tennessee, to lend his support to a strike by that city's sanitation workers. A sniper killed him while he stood on the second-story balcony of the

I submit that an individual who breaks a law that conscience tells him is unjust, and who willingly accepts the penalty of imprisonment in order to arouse the conscience of the community over its injustice, is in reality expressing the highest respect for the law. • **Martin Luther King Jr. (1929–1968)**

National Archives.

Lorraine Motel. His death touched off rioting in over one hundred cities across the country. More importantly, it hastened the shift of the civil rights movement toward violent confrontation, followed by its splintering in the 1970s and slowing in the face of backlash against affirmative action beginning in the 1980s. Part of this is attributable to King's elevation over the years to martyr status. Some scholars and social activists have argued that this deification has caused the civil rights movement to lose sight of the grassroots efforts necessary to effect social change, and has diluted King's own message of economic justice. Nonetheless, that his legacy can still spark such debate decades later testifies to his continued social and political relevance.

Kinship

Sociologists who study kinship patterns examine how different cultures and societies define and value kinship, whether through blood ties (procreation and marriage) or through bonds among groups who hold reciprocal interests in nurturing and sustaining themselves. Debates about what are misleadingly considered “tribal” forms of kinship spark modern discussions about the roles of mothers and fathers in modern society.

In the most basic sense the word *kinship* refers to the connections people have through family—by blood (procreation) and marriage. Thus defined, *kinship* is reducible to parent-child, sibling-sibling, and spouse-spouse relationships, and it extends to include other family members—grandparents, aunts, uncles, cousins, and in-laws. But people often claim or evoke kinship with others through a community of shared or common interests, especially regarding nurturing and sustenance. Sociologists who study kinship presume differing views on how kinship can be perceived and valued in a particular culture or society, while data from anthropologists contributes input to current discussions about modern-day family structure.

Constructionism

Constructionists—sometimes called “cultural constructionists” or “social constructionists”—posit or assume that people create their conceptual worlds with minimal influence from outside other than through power relations. They hold that the procreative basis of kinship is an ethnocentric illusion. They point out that kinship ties in various parts of the world are created by non-procreative means. Foremost among

these means are co-residence, food sharing, and food giving, with nurturance through adoption being perhaps a special case of the first and third means. Thus, in many Inuit (Eskimo) communities adoptive parents are referred to as (the English equivalent of) step-parent or foster parent. In Papua New Guinea genealogies are frequently adjusted to transform non-kin into kin when they become co-residents. In parts of east Africa a man in his travels may befriend another man, with whom he may perform a ceremony wherein each drinks the blood of the other. By this act the two men are said to be “brothers.” Constructionists rightly emphasize the importance of sharing in such cases. Thus, in the Inuit example of adoption the adoptive mother’s breast milk will go to the child if he or she is still an infant, and the mother supplies other foods if the child is older. In the Papua New Guinea example the sharing of food is likely to be more evenly balanced. In the east African example food is also shared, most conspicuously in the form of blood.

Focality

Constructionists almost entirely ignore, by contrast, the issue of focality. Consider the Inuit example. The terms assigned to Inuit adoptive parents are, as noted, based on parent terms, much like the expressions *foster parent* and *step-parent*: all refer back to procreative parents, who provide the focal points for these latter expressions. We can say much the same for genealogy manipulation in Papua New Guinea: non-kin are thus regarded as procreative kin, such that these latter people serve as the bases or foci from which kin classes are extended. In east Africa two men who drink each

other's blood are imitating postnatally what is true—and is thought to be true—of real brothers natally—that is, sharing blood. In all these cases—and many others—non-procreative kinship notions are modeled on procreative ones.

Ethnoembryologies

Constructionists and non-constructionists alike will insist that the term *procreative parents* be understood to refer to parents according to a local culture's appreciations of human reproduction or "ethnoembryologies." They are likely to point out that, even in Western civilization, the modern scientific finding that both parents contribute equally to the fetus is only about a century old, before which time it was maintained—although not unequivocally—that the father's sperm contained a miniature person, who was merely incubated in the mother. This notion, in fact, is a common ideology outside the West as well. Other variations exist. Probably the two most common of these are (1) that the mother supplies the soft parts of the body, the father the bones and (2) that the mother supplies the entire body, whereas the father either supplies the spirit or acts as an intermediary between the carnal world and the spiritual world. Thus in parts of Aboriginal Australia the father is said to "find" the spirit of his yet-to-be-born child in a dream and to direct it from there to the mother's womb. From this example it might seem misleading to refer to this role with the term *father*; the reasons why it is not misleading in the next section. Here three points need to be made.

First, the carnal-spiritual dichotomy is often violated by the special treatment accorded the bones, which, although of the body, decay only gradually and thus are likely to evoke notions of durability and permanence, like the spirit. Thus, in Aboriginal Australia the corpse is buried soon after death and disinterred after a year or so, at which time the flesh that remains is removed and discarded. The bones, by contrast, are retained: they are placed in a hollowed-out log decorated with emblems signifying the deceased's spiritual heritage, and the log-cum-bones is carefully hidden on the same tract of land

on which his or her father first encountered his child's spirit. The attention given to the bones of relatives and saints in the great religions of the East and West provides more familiar examples of much the same kind of thinking.

Second and even more important, two or more ethnoembryologies may exist in the same community. Among Aboriginal Australian men with whom researchers have talked, some argued for variation (1) noted earlier, others for variation (2), still others for both on different occasions. Statements that imply that all persons in a community believe the same thing fail to appreciate the richness of human experience and variation.

In fact—and this is the third and most important point—we may question whether the term *belief* helps us to achieve this appreciation. Older Aboriginal men in the Western Desert of Australia stress the "finding" experience noted earlier, whereas women and younger men make it plain that sexual intercourse is necessary for conception. Moreover, the younger men are quieted on this subject by the older men, who control the most important religious knowledge and who refuse to discuss sexual matters, insisting on the importance of "finding." An unwillingness to mix carnal and spiritual discourse, an overriding of tacit knowledge by dogma, seems to be involved here. However, tacit knowledge implies a presence, not an absence.

Ignorance of Physical Paternity

Failure to recognize this caused the first anthropologists who worked with Aboriginal Australians to conclude that these people are, as it was once phrased, "ignorant of physical paternity." This mistake was not innocent. It fed Victorian typologies (classifications based on types or categories) about "primitive society" and, later, racist ideologies concerning the alleged intellectual inferiority of Aboriginal Australians. Its early twentieth-century equivalent was a comparable claim for the Trobriand Islanders, off the northeast coast of Papua New Guinea. Subsequent research in the Trobriands has shown that this "ignorance" is, in fact, part of a dogma wherein groups of a certain kind create the illusion that they are self-perpetuating,

Relations are simply a tedious pack of people who haven't got the remotest knowledge of how to live, nor the smallest instinct about when to die. • Oscar Wilde (1854–1900)

that the spirits of the dead of these groups enter their women and are reincarnated through them in their children. In order to achieve this reincarnation, however, sexual intercourse with a nongroup member is nonetheless posited as necessary.

Matriliny and Patriliney

Victorian and early twentieth-century anthropologists who promulgated the “ignorance of physical paternity” idea linked it with the reckoning of kinship through women only—what has come to be called “matriliny” or “matrilineality.” After all, if paternity were unknown, the reckoning of kinship through men could not occur. Moreover, they associated matriliny with “matriarchy” or rule by women. Within anthropology these ideas were dispelled by 1930, largely by research in the “matrilineal” Trobriands by the Polish anthropologist Bronislaw Malinowski (1884–1942). More recently, however, certain feminist thinkers have resurrected them. So it is useful to revisit some of what Malinowski and his cohorts discovered.

First, kinship everywhere is reckoned through both parents—that is, bilaterally—according to one or another theory noted in the discussion of ethnoembryologies. Where kinship reckoned solely through women applies, it does so for certain purposes only, and these purposes vary considerably from one such community to another. Where matrilineal groups exist, they may or may not have great importance in everyday life, but even if they do, the expression *matrilineal society* oversimplifies and misleads.

Second, it can be argued that matriarchies do not exist. Men tend to dominate women everywhere, although great variation exists in the extent to which—and the circumstances under which—they do so. The “goddess” imagery espoused by some feminists is not consistent with the status of flesh-and-blood women. If anything, age—not gender—is the more important criterion cross culturally for assuming authority: the world tends to be run by relatively healthy people older than forty.

Today, some feminists also have taken over the Victorian narrative of the “evolution” of patriliney—or

patrilineality—from matriliny, and again “ignorance of physical paternity” is key. When men (so the narrative goes) somehow finally realized that they, too, have a role in conception, patrilineal kin reckoning became possible, and it replaced matriliny and matriarchy with patriliney and patriarchy. But the following factors must be considered.

First, in communities with patrilineal groups, as in all others, kinship is reckoned through women as well as men.

Second, although the position of women is generally higher in communities with matrilineal groups than it is among those with patrilineality, the latter are at least as varied as the former.

Third, probably the most radical of these variations is that between groups with lengthy patrilineal genealogies and those with minimal genealogical reckoning, such that being the child of one’s father is sufficient to attain membership, and the unity of the group is expressed nongenealogically, or through genealogical metaphor. Researchers in a part of Aboriginal Australia, for example, found that some Aboriginal people were said to be reincarnations of parts of a Primeval Rock Python, others of parts of a Primeval Crayfish, still others of parts of a Primeval Duck. The father—but not the mother—of each such individual was also said to be Rock Python, Crayfish, or Duck, as the case may be, but the genealogical relationship among (for example) Rock Python people was largely unknown and for most purposes irrelevant. Such groups have matrilineal analogues in other parts of the world.

Fourth, at the other extreme are notions of patriliney that assume the entire ethnic unit—indeed, in some cases the entire world—is composed of the descendants of a single primeval creator or a set of brothers. The Bible, for example, stipulates that everyone on Earth is descended from one or another of Noah’s three sons, and ideologies of this sort are common in the Muslim Middle East of today and in adjoining parts of sub-Saharan Africa. With large populations, of course, no attempt to relate everyone by detailed patrilineal links is possible. No matrilineal analogues exist.

Fifth, in communities with patrilineal groups, as in those with matrilineal groups and in those, like

most in the West, with no such groups, social life is most penetratingly seen as involving human beings acting in various recognized capacities. Thus a title, such as “professor of anthropology,” is relevant when one is in academic settings but not when one rides the New York City subway. “Tribal” communities do not have subways, gyms, and stamp dealers, but they have more than just patrilineal or matrilineal groups. In fact, the term *groups* is probably more than a little misleading: it suggests a boundedness and a permanence that are, literally, out of this world. Nowadays most anthropologists have abandoned the heavy reliance of their predecessors on what one critic has dubbed “groupology,” but it survives in feminism and other influences on modern life.

Kinship and Modern Life

Forms of kinship, like everything else, have histories. Of particular importance to present-day kinship studies—and modern life more generally—are the new reproductive technologies that, among other things, allow women to bear children without male parental behavior other than insemination. Such technologies may suit some women, but what is their impact on the raising of children? Considerable research suggests it is not entirely positive. People in the Western world have a long record of looking to anthropological data from the “tribal” world to suggest alternative modes of living, the range of human possibility. But advocates of fatherlessness (in the noninseminatory sense) will find little if any relief in such data. In approximately 85 percent of “tribal” communities both parents co-reside with their dependent children, and in virtually all of the remaining 15 percent, in which fathers are not present, close male kin of the mothers are. The media slogan “Families come in all shapes and sizes” is not much supported by these data.

Moreover, in many biparental communities, a pattern exists that has been termed “aloof fatherhood.” In these communities there are elaborate ideologies about the alleged destructive and/or polluting powers of women; these ideologies lead men to distance

themselves from their wives spatially (usually in designated “men’s houses”) and emotionally. Some people have suggested that this aloofness of the husbands encourages women to turn to their young sons for emotional warmth, but this quest is not an entirely welcome one. Growing boys are likely to experience it as an attempt to annihilate their emerging male selves, to retain an unconscious sense of female gender identity, and to reproduce their fathers’ fantasies and behavior concerning women. Indeed, “men’s house” rituals nearly always involve the imitation by men and boys of some aspect of female reproductive behavior, most commonly a sort of “pseudo-menstruation” effected by letting blood. Unsurprising, too, is a recurrent myth-pattern, wherein a primeval age is posited in which current gender roles are largely reversed. This myth-pattern, incidentally, has fueled modern “matriarchy” theory, but we probably more accurately can see it as a projection onto local notions of “history” of the power relations that boys experience with their mothers under “aloof fatherhood.” Finally, a part of this complex is an exaggerated belligerence that some scholars have called “protest masculinity.”

This last characteristic most importantly connects “aloof fatherhood” in the “tribal” world to the growing incidence of fatherlessness in modern households—what some scholars have called our most urgent social problem. Adolescent boys raised without fathers are far more likely to commit violent crimes than are other boys, even if one controls for other factors (e.g., race, household income). Among these crimes are the physical and sexual abuse of women and children. Moreover, such boys are also much less likely later on to commit themselves to relatively permanent reproductive relationships with women. Many thoughtful people—of both genders and all positions on the political spectrum—are concerned about such modern-day trends.

Knowledge Economy

One of the most fundamental properties of human social existence is distributed knowledge. While knowledge resides, in the final analysis, only in the human brain, it needs to be shared with others and distributed in order to be effective. This process embodies what is known as a knowledge economy.

Put simply, no one can know everything, and so cooperation among people consists of sharing necessary knowledge. Historically, one of the main characteristics of commercially and technologically sophisticated societies has been the fine degree to which knowledge is divided; the degree to which labor is divided is to a large extent derived from the division of knowledge. A knowledge economy is thus based on creating, evaluating, and trading of knowledge.

There are many ways to cut and classify the kinds of knowledge people need to possess and exchange. One appealing way is to divide the information up into those parts that deal with social matters and human affairs and those that concern the external environment. These roughly correspond to the spheres of *exchange* and *production*. While the sphere of exchange contains *allocative knowledge* such as “where do I hire a pipe fitter,” “what is the price of bread,” or “how do I purchase the stock of Microsoft,” the sphere of production contains mostly statements about the physical and biological environments in which people operate.

Technology concerns the latter sphere: it consists of information that regards natural phenomena and the rules and regularities we can formulate about them. It includes statements like “the Mississippi flows from north to south” and “it snows in the winter in

Michigan” as well as Schrödinger’s wave equations. Science is a small subset of this set of knowledge, which can be termed *propositional knowledge*, but the hallmark of the modern age is that its relative importance in the knowledge economy has risen steadily.

Allocative Knowledge

The ways society has used information to allocate resources and reproduce itself involve some of the central questions of economic history. Information about exchange is summarized effectively in market economies by the price mechanism. In a classic article published in 1945, the economist F. A. Hayek pointed out that in market economies a mind-boggling amount of information is summarized and processed by the price mechanism. The typical consumer of a meal of sushi in Evanston does not have to know where the fish was caught, how it was processed and shipped to Illinois, and how it was cooked: by paying the price of a meal, all this information is summarized and processed by people the consumer does not know and does not have to know. On the other hand, the Japanese wholesalers processing the tuna do not have to know or care who precisely wants to eat what.

Free decentralized markets are neither tools of exploitation nor miracle cures for all of society’s ills; they are above all information-cost-saving devices. Once markets are disrupted or abolished, as happened in Marxist command economies, this information has to be processed consciously by officials, who set prices by decree rather than through competitive processes. The results have been devastating.

Money played a unique role in increasing the informational efficiency of societies, since money served

Information is religion's greatest enemy, and in an age when information is just a few keyboard strokes away from anyone with a computer, this is going to pose a greater threat to Christianity than anything it has yet 'survived.' • **Farrell Till (b. 1933)**

as a unique unit of account and thus made exchange easier. Without a means of exchange, trade would require a double coincidence of wants, which is informationally more cumbersome. Money also provides a measure of value, thus providing different goods with a common denominator, which lubricates the exchange process. It is now widely recognized that decentralized and unregulated markets are the most efficient information-processing social tools in our arsenal. Even when they misfire and create inefficient outcomes, the remedies are often worse than the maladies.

The degree to which societies allocate resources through markets rather than through central planning or another allocation mechanism (such as intra-tribal allocation by the whim of the leader) and the way allocative knowledge is processed and distributed determine to a great degree the social and economic development of a society. Market economies on the Eurasian continent developed, by and large, to a greater degree than those in Africa, Oceania, and pre-1492 America. In western Europe market allocations were highly developed in Roman times but for a variety of reasons declined in the second half of the first millennium, whereas the Islamic Middle East and China were in that sense far more developed.

Parts of western Europe recovered during the Middle Ages, and markets became increasingly important in processing allocative information, with prices of both locally and internationally traded goods increasingly effective in indicating both information about the scarcity (supply) and desirability (demand) of commodities. Moreover, the same kind of decentralized market processes began to control the allocation of labor and land, extending the coordinating role of markets to the factors of production.

In the nineteenth century, even capital markets became increasingly competitive, although in those markets the processing of information was often problematic and inefficient because of informational asymmetries between lender and borrower, and the performance of different economies was often influenced by the functioning of their capital markets.

Allocational information is of course constrained by how well it can flow over communication channels. People wrote letters, and while the postal system was far from perfect, all information societies have found ways of communicating over long distances. Information is the lightest of all cargoes, but it still needs to be moved. Short of unusual forms of optical communication—like smoke signals, the Chappe semaphore telegraph introduced in the late eighteenth century, and the use of (expensive) homing pigeons—information moved with people. Until the nineteenth century, then, the speed of information flows was only as fast as a horse or a ship could travel. This limited the effectiveness of the price mechanism for many goods and services, and before 1800 or so most prices did not converge between regions, a telltale sign of less-than-perfect information flows.

With the introduction of railroads in the early 1830s and the telegraph a decade later, the age of informational globalization truly began. Interest rates and wheat prices quickly converged across the Atlantic after the transatlantic telegraph cable was laid. Despite disruptions due to political upheavals in the twentieth century, the trend toward globalized allocational information has continued. Securities and commodities markets demand that traders and investors have access to highly specific data more or less instantaneously.

The telegraph was a huge step forward, possibly the greatest discontinuity in information transmission in relative terms, but it was gradually displaced by the telephone, by teletexts of various kinds, and eventually by a vast electronic network of information that guarantees the effective operation of markets. This does not mean that these markets deliver the most efficient of all possible worlds, only that arbitrage opportunities do not persist.

Propositional Knowledge

Propositional knowledge was in many ways equally fundamental to the economic performance of society. Whereas commercial exchange societies demand a great deal of information about availability and

A fragment of the Codex, a collection of bark books used in prequest Mesoamerica to classify and organize information. Photo by Chris Howell.

desirability (summarized in prices), this information is not truly indispensable. On the other hand, figuring out the regularity of seasons and plant and animal life was already a knowledge requirement for hunter and gatherer societies. In some sense all modes of production—whether agriculture, manufacturing, or service (such as medical services and transportation)—involve the manipulation of natural phenomena and regularities. And effective manipulation depends on information. Every production technique involves a set of instructions on how to grow potatoes or operate a nuclear power plant. Such instructions require some prior knowledge of the phenomena on which they are based.

Much of economic history can be viewed as the slow evolution of information toward increasing specialization and a finer *division of knowledge*. Engineers, chemists, mechanics, and physicians controlled specialized knowledge, and as the body of knowledge expanded—at an exponential rate during and after the Industrial Revolution—finer and finer specialization was necessary. This implied that individuals needed to have better access to knowledge that was already known to someone in their society. The access to this knowledge depended historically on the technology of knowledge reproduction as well as on cultural factors.

The great discontinuity here was the printing press, which created a bridge between “town and gown” (the non-academic and the academic), but the effectiveness of the printing press as a means of disseminating

information depended on the degree of literacy as well as on the nature of the books printed. As long as most books were concerned with religious issues or were romance novels, their impact on economic development was of course marginal. But in the sixteenth century a technical literature concerned with placing existing information at the disposal of those who needed it at a minimum cost started to evolve.

In other forms, too, the Enlightenment in the West was an information revolution that changed many of the parameters of information flow. Specialization had its costs: from classical times on, philosophers and scientists had moved in different spheres than people like farmers and artisans who produced useful things. As a result, economically productive people were rarely aware of best-practice science, and scientists were rarely interested in the day-to-day problems of production and did not apply their intellects to the resolution of these problems. For China, so rich in scientific knowledge, this was especially true, but it also held for classical antiquity where brilliant scientists and mathematicians such as Archimedes and Hipparchus did not bother with issues dealing with agriculture or manufacturing. This started to change in the medieval Occident, when monks often became leading scientists and technological innovators.

The gap between the two narrowed further after the European voyages, and historians date the closer communications between the two to the middle of the sixteenth century. The use of printed books to disseminate technical information coupled with rising literacy rates and the wider use of paper facilitated these bridges between people who knew things and those active in actual production. Thus, for instance, the celebrated book published by Georgius Agricola, *De Re Metallica* (1556), which summarized what was known at the time in mining engineering, and Jacques Besson’s *Theatrum Instrumentarum et Machinarum*, published in Latin and French in 1569, went through three translations and seven editions in the following thirty-five years. While these precedents were important, the true information revolution came in the eighteenth century with the Enlightenment, which eventually changed the entire process of

technological progress and culminated in the Industrial Revolution.

The Industrial Enlightenment

The informational aspects of the Enlightenment are a central element of the economic and social changes triggered by technological progress. In the eighteenth century, a movement we can term the Industrial Enlightenment, led to a three-pronged change that had far-reaching economic results. First, the sheer number of serious scholars engaging in scientific research in the West increased steadily after the triumphs of Galileo and Newton, whose insights vastly augmented the social prestige of natural philosophers. Second, the research agenda of these scientists increasingly included topics that might benefit the “useful arts” such as chemistry, botany, optics, hydraulics, and mineralogy. In many of these fields, to be sure, science was too little advanced to be of much immediate benefit, but many of the promissory notes issued in the eighteenth century by scientists committed to the Baconian program of controlling nature through understanding it were honored in a later age.

Third, a central goal of the Industrial Enlightenment was to diffuse knowledge. It did so by publishing accessible and user-friendly compilations of knowledge, from books of a general nature like encyclopedias and technical dictionaries to specialized technical manuals and textbooks. The age also saw a meteoric rise in the publication of scientific periodicals, reviews, and abstracts of important work, and there is ample evidence that these periodicals were read by contemporary engineers and inventors. The paradigmatic document of the Industrial Enlightenment was no-doubt the *Grande Encyclopédie*, which was filled with technological information on such mundane subjects as glass-blowing and masonry, accompanied by highly detailed and informative diagrams. The need for “search engines” was felt acutely, and increasingly ingenious engines were developed.

Knowledge was also distributed through informal networks and personal contacts, to a degree

we can only guess at, since most of those contacts have left few records. One such organization about which a lot is known is the Lunar Society, a private club in Birmingham, England, in which some of the best scientists of the age discussed useful knowledge with leading entrepreneurs and engineers. Hundreds of learned societies were established in Europe in the eighteenth century, and while not all could boast the quality of the minds that attended the Lunar Society or the inappropriately named Manchester Literary and Philosophical Society, they all reflected a profound change in the attitudes toward, and organization of, useful knowledge in the West.

Moreover, in this age markets for expertise and technological knowledge also emerge. Much of the work of the great engineers of the time, from John Smeaton and James Watt, consisted of what we would now call consulting. The exact impact of these changes on economic progress is still a matter of some dispute, but its coincidence with the economic takeoff in the West in the nineteenth century can hardly be happenstance.

The Explosion of Access Technologies

In the past two centuries, the role of useful knowledge in society that the Enlightenment pioneered has exploded, to the point where science can be said to have replaced religion in many areas as the central intellectual force determining social development. Modern science and the technological progress it spawned became dynamic elements in world history in the twentieth century. What is notable is not just the vast growth of knowledge of natural phenomena but also the appearance of many new social and technical means for its dissemination: the technical handbooks and dictionaries of the late eighteenth century grew enormously. Historians estimate that in 1800 only about one hundred scientific journals were published—this has grown into a gigantic mass of about twenty thousand scientific journals, not including journals in engineering and other applied sciences. Huge compilations of detailed and highly

specialized information, including catalogs and databases too gigantic for any individual even to comprehend, have been put together with the help of powerful computers.

Access to this information is relatively cheap and sophisticated means exist to select the wheat from the chaff. What made this possible is a combination of changes in the organization of knowledge and the sociology of science, coupled with radical changes in the access technology. Scientists have become a self-policing community, which through complex processes of persuasion and proof establish consensus, always challenging and at times replacing them. Markets for information have become increasingly efficient and widespread, with consultants of all kinds becoming an integral part of the “knowledge society.” In this kind of world, access to what is known by others is essential. But this world also raises many issues of verifiability, reliability, and authority.

Among the many changes in access technology, the Internet, which consists of increasingly sophisticated libraries, more specialized textbooks, summaries of scientific papers, and popularizations of scholarly textbooks, is the crashing climax of two centuries of improving access technology. Early computerized databases evolved into the search engines of today, in which mammoth amounts of knowledge can be accessed by anyone, essentially at zero cost, through such databases such as Medline and Econlit.

Kongo

Portuguese interest in the central African kingdom of Kongo began in 1493 with copper, and soon turned to slave trade. The Kongo achieved wealth and power by participating in this rising global economy, but declining local communities were exposed to French and Belgian colonization in the late 1800s. Sudden decolonization in 1960 and an unusual wealth of natural resources have resulted in the long-term destabilization of the region.

Comparatively little is known of the history of the kingdom of Kongo in central Africa before contact with the Portuguese in 1483. Sometime between the ninth and fourteenth centuries political centralization began, based on the control of intersecting regional trade routes and commodities such as salt, iron, and copper, as well as *nzimbu* shells, which served locally as currency. Taxation provided the necessary revenue for state building, and the redistribution of resources and performance of a royal cult generated loyalty to the king.

With the arrival of the Portuguese, the region's history became inextricably linked with the trans-Atlantic slave trade. The Kongo kingdom rose to unprecedented wealth and power through its participation in the newly arising global economy. But it was this overseas connection that devastated local communities, and, in the second half of the seventeenth century, caused its decline, fragmentation, and eventual replacement by trade networks that operated through localized power centers.

Kongo is a name derived from the local language Kikongo after which the capital city of the kingdom, Mbanza Kongo, located above the banks of the largest

river in the region, the Congo River, was named. When the Belgian king acquired a colony in the region in 1879, it was called the Congo Free State and, from 1908, the Belgian Congo. With political independence in 1960, the former Belgian colony and the neighboring French territory both named themselves after the kingdom.

The Kingdom of Kongo and the Portuguese

In the second half of the fifteenth century, the Portuguese explored the African coast mainly in order to find a sea route to Asia. They also hoped to gain direct access to the gold imported to Europe from Africa, a trade at the time under Italian hegemony. With limited knowledge of central Africa, the Portuguese identified the Kingdom of Kongo as a potential region of gold deposits and avidly pursued this mistaken notion throughout the sixteenth century.

The first contact was made in 1483, when a Portuguese ship's crew kidnapped Africans and brought them to Europe to gain the information that might facilitate their interaction with the kingdom. Two years later, a second expedition was sent to central Africa. This time the Portuguese ventured to offer the king of Kongo what they considered to represent civilization: a shipload of cloth, clothes, tools, horses, Portuguese men engaged in professions ranging from priests to craftsmen, and Portuguese women who were intended to teach the Kongolese the virtues of Christian housekeeping. The king, when presented with the gifts, recognized in these visitors an opportunity to advance his own power and that of his political elite. He carefully weighed the means of furthering

this ambition and settled on Western-style education and Christianity in addition to the import of luxury goods in exchange for copper and, beginning in the sixteenth century, slaves. From this point an ambiguous relationship between Portugal and Kongo began to unfold.

Kongolese society was socially organized in three strata: the court, the villagers, and the slaves. The court was centered on the king, who ruled by delegating power to provincial governors. The latter were responsible for local administration, which involved taxation, the capture of slaves, and mobilizing a standing army that in the sixteenth century consisted of sixteen thousand to twenty thousand slaves. A royal council, with both men and women as members, assisted the king. Once the Portuguese had established their presence in the kingdom, they frequently became members of Kongolese society through marrying women of the nobility or serving as mercenaries. There is even a case, that of Duarte Lopez, in which a Portuguese man became a gentleman of the court and eventually the king's ambassador to Europe.

Initially, the Portuguese focused on the trade in copper, but the trafficking in human beings played an ever more important role. First slaves were exported to the Atlantic sugar islands of São Tomé and Príncipe just off the African coast. Then, from the early sixteenth century, they were taken to the Caribbean and the Americas. By 1530 Kongo annually exported four thousand to five thousand slaves. The increase in numbers contributed to an expanding cycle of violence, with more and more random trade interactions and military raiding campaigns. This was only aggravated when the Portuguese attempted to bypass royal control of the slave trade. They intended to increase their profit margin in part by avoiding paying trade taxes.

Decline

Several factors contributed to the decline of Kongo. The king had exercised a monopoly on the import of luxury goods, which he redistributed to the elite in order to ensure loyalty. But Portuguese traders began to deal directly with local communities, something about which the Kongolese king Afonso I (reigned 1506–1543) complained bitterly in letters to the Portuguese monarch as early as 1526. In this early period of the trans-Atlantic slave trade many of the women, men, and children were enslaved within the kingdom, but the Portuguese indiscriminately bought and branded slaves who were followers of the king and often stood under his protection. By the 1560s the slave trade was causing such severe tension within the kingdom that in 1568 Kongolese villagers joined warriors, probably from the south-east of the kingdom, known as Jaga, who, it appears, initially invaded the kingdom in order to raid for slaves and food, but who proceeded to attempt to destroy the kingdom and to control the slave trade. The king and his followers finally defeated the Jaga with Portuguese assistance in 1569. After that war, in 1575, the Portuguese founded the colony of Angola just south of Kongo, which deprived the kingdom of its regional hegemony over the trade routes. Although

*"And this also," said Marlow suddenly [referring to England, as he began to tell the story of his journey up the Kongo River], "has been one of the dark places of the earth." • From *Heart of Darkness* by Joseph Conrad (1857–1924)*

it did recover politically for a short time, the arrival of Capuchin missionaries in the second half of the seventeenth century undermined another source of royal power when the king lost control over Christianity as a royal cult. Power gradually shifted from the kingdom's administration and political structure to local trading houses. In 1665 Angolan military forces defeated the kingdom militarily. After the death of King António I that same year, a series of succession struggles ensued.

An unlikely figure mounted a final attempt to politically unify the kingdom: a young Kongolesse woman, Doña Beatrice (1684–1706), who in 1704 had a vision of Saint Anthony. Afterward, as a prophetess, she founded an independent church and political movement with an emphasis on Africanization and political unification. Doña Beatrice assembled thousands of followers in the ruins of the former capital city. After she gave birth to a son, the result, she claimed, of immaculate conception, political opponents and the Catholic Church pursued her. In 1706 the latter burnt her at the stake as a heretic.

Implications

The Congo region provides both a historical example of African state building and of the devastating results of African societies' involvement in the trans-Atlantic slave trade. The long-lasting effects of political decentralization and fragmentation in the entire region in the seventeenth century are partly responsible for the lack of resistance to Belgian and French colonization efforts in the late nineteenth century. The outstanding brutality especially of early Belgian colonialism and the suddenness of decolonization in 1960, together with an unusual wealth of environmental resources—including uranium, diamonds, and copper—have re-

sulted in the long-term destabilization of the region, sadly continuing into the twenty-first century.

Korea

The Korean peninsula is located at the eastern edge of the Asian continent, with the Yellow Sea on one side and the East Sea on the other. Although scholars have subsumed Korea's history into discussions of East Asia (primarily China), Korean kingdoms and dynasties interacted with foreign powers long before modernization in the late nineteenth century. Today the peninsula is divided into two Koreas, North and South.

Evidence for the existence of human beings in the Korean peninsula can be traced back to about 700,000 years ago, to the foraging (Paleolithic) era. The Neolithic period, in which sedentary life began, started from almost 10,000 BCE. The first state established in Korean peninsula was Old Choson (Joseon); its mythical founding year is said to be about 4,300 years ago, and historical records confirm that it existed around the seventh–eighth century BCE. Since then, the Korean peninsula has experienced the rise and decline (during the Three Kingdoms era) of the states of Koguryo (37 BCE–668 CE), Paekche (18 BCE–660 CE), and Shilla (Silla, 57 BCE–935 CE), whose rule overlapped; the Unified Shilla (668–935 CE); the Balhae (698–926 CE); the Koryo kingdom (918–1392); and the Choson dynasty (1392–1910).

Until the nineteenth century, scholars traditionally discussed the history of the Korean peninsula in the context of the international order of East Asia, primarily the Chinese tributary system, a basic mechanism for forming diplomatic relations with neighboring countries. As a result, it was widely assumed that Korea engaged with the world as a whole only after

its opening and modernization in the late nineteenth century.

But Korean history demonstrates that Korea constantly interacted with other Asian countries and other parts of the world even before the modern period. Korea imported Buddhism and many aspects of material culture from India and Central Asia and also interacted with Arabic countries. Western culture was introduced during the Choson dynasty. Indeed, diverse exchanges with the outside world were indispensable for the development of Korean traditional culture.

Encountering the World: Prehistory–1392

The contact zone of Korea with the rest of the world during the Neolithic and Bronze Age reached as far

An anonymous artist painted this bird's-eye view of a small village near Korea's northern border, circa 1800.

as Siberian steppe culture, China, and Japan. The comb-pattern pottery used by Neolithic people in Korea seems to have been brought into the peninsula by Asian people from the Siberian steppe region. Bronze Age remains of more than 30,000 dolmen (single-chamber megalithic tombs) in the Korean peninsula are similar to the ones found in Liaoning in northeastern China and Kyushu in western Japan. This confirms that exchanges between these regions formed a common cultural sphere.

Cultural interaction expanded after the Iron Age during the Three Kingdoms era. The Three Kingdoms of

Koguryo, Paekche, and Shilla adopted Buddhism circa the fourth century. Before that, belief systems were mainly shamanistic. Buddhism seems to have been introduced by Chinese or Indian monks via China. In the era of Unified Shilla, Korean monks such as Haecho went on pilgrimages as far as India and Arabic countries.

It is noteworthy that historical records from the period of the Three Kingdoms and the era of Unified Shilla refer to various glass products and imports from Persia and Southeast Asia. Samguk sagi (The History of the Three Kingdoms) mentions wool carpets and rugs from Persia and luxury goods from Southeast Asia. These commodities seem to have been imported through direct trade because there is some evidence of personal contacts. For example, in the painting of wrestling (Ssireum, or Korean traditional wrestling) on a Koguryo-era tomb mural, one of the wrestlers has an exotic appearance with big eyes and an aquiline nose. The stone statue of a military man standing in front of the Unified Shilla royal tomb called Kwaer-eung also looks foreign. It is likely that the figures were either Central Asian or Arabic.

Cultural interactions predominated with the Chinese, but were also closely linked to the maritime trades of Arabian merchants. In the seventh century, the Islamic region began its contacts with China. According to eighth-century Chinese records, south China was linked to trading routes in Indonesian waters, the Indian Ocean, the Persian Gulf, and the east African coast. The Three Kingdoms and the Unified

Shilla may have used these sea routes when they traded with Arabian merchants.

The Anthology of Great Buddhist Priests' Zen Teachings (Jikji), published in 1377, is the earliest known book to be printed with moveable metal type.

The Silk Roads connecting China and the Western world was another important route for exchange. Koguryo envoys can be seen in the mural that depicts the reception of twelve foreign envoys in the mid-seventh century, discovered at the site of Afrasiab in the outskirts of Samarqand in Uzbekistan in 1965. We can infer that they were Koguryo envoys if we consider their ethnicity, dress, and the international relations of that period. They had reached Samarqand via the northern steppes in order to establish an alliance. The Three Kingdoms formed diplomatic relations not only with China but also with numerous ethnic groups and states in the northwestern steppe regions. By doing so, they were able to sustain their survival and their position as one of the axes of the East Asian order.

The Koryo kingdom (918–1392) engaged actively in international trade networks that reached as far as Arabia, and imported Indian cotton, sugar, ivory,

and dyes from the south. Koryo's historical records refer to Arabian merchants who came to the kingdom; the name "Koryo" was known to the Western world, and the modern name "Korea" is derived from it.

The Koryo fought with the Mongols for forty years. As a result of their eventual defeat in 1270, Koryo experienced Mongol intervention in its domestic affairs for a long time. While Koryo was politically controlled by the Mongols during this period, they could interact with the Islamic world through the Mongols and import information and knowledge, such as the calendar from Islam. The Map of Lands and Regions of Historical Countries and Capitals produced in 1402 in the early Choson era, was based on geographical knowledge from Arabia. The map shows the territories of the world and their capitals, and includes China, the Korean peninsula, Japan, Siberia, Southeast Asia, India, the Arabian Peninsula,

The Kangnido map, a Korean map of the world made in 1402, demonstrates that Korea constantly interacted with other Asian countries and other parts of the world before the modern period.

Africa, and Europe. This map demonstrates Koryŏ's rich understanding of world geography.

The Koryŏ kingdom must be mentioned in the history of the print technology of the world. Print technology was developed from the early period in Korea, and the Great Dharani Sutra of Pure and Immaculate Light is the oldest existing book printed from woodblock type. This tradition might have contributed to the development of metal movable type. The Prescribed Ritual Text of the Past and Present was printed in 1234 using metal movable type, but this text no longer exists. The Anthology of Great Buddhist Priests' Zen Teachings (*Jikji*), published in Cheongju in 1377, is the oldest surviving book published using metal movable type. It is stored in the French National Library. The use of metal movable type in Korea occurred seventy-seven years earlier than Gutenberg's use of movable type printing. The Koryŏ kingdom's technology provided a foundation for the development of the Chosŏn dynasty's high quality of metal movable type technology.

Foreign Relations during the Chosŏn Dynasty

Foreign policies of the Chosŏn dynasty (1392–1910) were influenced by the closed-door policy of the Ming dynasty (1368–1644). In addition, Japanese pirates

had been thriving from the late Koryŏ period, and occasional trade with Southeast Asia came to an end because of Japanese piracy. Thus, Koreans interacted with foreign countries (except for China and Japan) only intermittently, and with foreigners, via shipwrecks for example, in sometimes difficult contexts. (The shipwreck of the Dutch *jaght* [yacht] *Sperwer* in 1653, and the forced detainment by the Chosŏn government of Hendrick Hamel and thirty-six other survivors for thirteen years, attracted the attention in the Netherlands and the West when Hamel, after escaping to Japan, published a journal about this experiences in 1668.)

Korea under the Chosŏn dynasty was not completely isolated, however, for it still communicated with the Western world, and acquired Western goods, through China. Catholicism was introduced in the seventeenth century. Korean envoys to Beijing home brought news of the scientific and religious writings of the Italian Jesuit missionary Matteo Ricci, who was then stationed in China. At first, Catholicism was accepted as a form of scholarship, but later, as a religion.

In the nineteenth century, China revealed its weakness to expanding Western imperialist powers in East Asia. The Chosŏn government began to waver in its perception of the West. Some Koreans, aware of Western intentions to invade, supported a maritime defense policy. Others advocated the

U.S. Air Force B-26
(Invader) light bombers
strike over North Korea.

adoption of Western technology for national interests. During this period of confusion, the Choson government signed the Treaty of Kanghwa with Japan in 1876, and concluded treaties with the United States, Britain, Germany, Italy, Russia, France and Austria. As a result, the dynasty started to develop modern international relations. Ultimately it failed to defend itself against the invasion of Japan, which was emerging as the most powerful nation-state in East Asia.

Modernization, Colonial Rule, and a Country Divided

Beginning in 1910, Korea experienced the frustration of modernization and Japanese colonial rule for thirty-six years. Right after its liberation in 1945, the Korean peninsula was divided at the 38th parallel and occupied by the Soviet Union army in the north and the U.S. army in the south. This was a reflection of the confrontation between the United States (the liberal capitalist bloc) and the Soviet Union (the communist bloc). This occupation ultimately resulted in the formal division of Korea: North Korea, officially

the Democratic People's Republic of Korea, with its capital at P'yongyang; and South Korea, officially the Republic of Korea, with its capital.

The Korean War in 1950 was an expression of these conflicts and confrontations. The Korean War took the form of a civil war, but it was essentially an international proxy war. And it was the same during the war and the truce talks. The war ceased not with a peace treaty but with an armistice. The war had a tremendous impact on modern Korean history.

South Korea has accomplished dramatic economic growth since the 1960s, a feat often called the "miracle of Han River." Further, South Korea overcame a hundred years of turmoil since its modern history began, and has successfully established and consolidated a democratic political system.

On the other hand, North Korea is officially a socialist republic, under its de facto leader Kim Jong-il; the country maintains strong ties to the People's Republic of China and its allies in Southeast Asia—Cambodia, Laos, and Vietnam. In August 2009, the government's disclosure of a uranium enrichment program caused great consternation among world leaders. Because of

Kushan Empire

The Kushan era (c. 45–230 CE) was one of the most important and influential periods in the history of ancient Eurasia. During the early centuries of the common era, the Kushans dominated the politics, culture, and economy of a vast region of Inner Eurasia.

Through its active engagement in Central Asian politics, economics, art, and trade along the Silk Roads, the Kushan Empire (c. 45–230 CE) exerted significant cultural influence upon a vast region of Inner Eurasia, including much of present-day Tajikistan, Uzbekistan, and Turkmenistan, the western edge of Xinjiang (in northwestern China), the whole of Afghanistan and Pakistan, and much of northern and central India. The Kushans were one of the key powers of their era during a period in which much of Afro-Eurasia was controlled by just four empires—the Han, the Roman, the Parthian, and the Kushan.

Despite their undoubted importance, evidence for the Kushans remains problematic. They produced no significant body of literature, and only a very few of their fragmentary inscriptions are known. Yet both the Yuezhi—a tribal confederation from whom the Kushans were descended—and the Kushans themselves are frequently mentioned in the literature of a wide range of contiguous societies, including Chinese dynastic annals, Indian, Tibetan, Persian, Manichaean, and Sogdian sacred and secular texts, Islamic histories, and several Greco-Roman sources. It is from this often incidental evidence that much of their history has been constructed.

Only a few examples of Kushan monumental architecture have survived, although seventh-century

Chinese sources attest to their construction of impressive palaces, Buddhist stupas, and dynastic sanctuaries. Archaeologists have uncovered evidence of substantial urban construction during the Kushan era, in both Afghanistan and Pakistan. In addition, the important Kushan-sponsored art workshops in Mathura (northern India) and Gandhara (northwestern Pakistan) and the discovery of international art collections near the royal palaces at Begram (Afghanistan) and Taxila (Pakistan) provide evidence not only of the Kushan monarchs' syncretistic approach to art production but also of the significant levels of trans-Eurasian cultural exchange that occurred during the Kushan era.

The most substantial evidence for the Kushans is numismatic. Kushan coins have been discovered in the thousands throughout the extent of their territory. They provide evidence of early cultural influences on the empire, military and political expansion, the genealogy of royal succession, religious and ideological beliefs, Kushan economic domination of the region, and the eventual dissolution of Kushan political control in the third century CE.

The Yuezhi and “Early Kushans”

The Kushans were descended from a tribal confederation known to the Chinese as the Yuezhi who probably spoke Tocharian, an Indo-European branch language. Han historians describe how the Yuezhi were crushingly defeated near Dunhuang by another tribal confederation, the Xiongnu, in 162 BCE. Forced to migrate away from their homelands in present-day Gansu (north central China), the Yuezhi eventually

relocated in Bactria (ancient Afghanistan) where they defeated the remnants of the Greco-Bactrian kingdom and some time during the first century BCE occupied Bactria in five tribal (*yabghu*) divisions. By 45 CE, Kujula Kadphises, a prince of the Yuezhi Kueizhuang (hence Kushan) tribe, reunited the tribes into a single powerful confederation and established the Kushan Empire.

The migration of the Yuezhi was directly responsible for the opening up of extensive Silk Roads trade and subsequent trans-Eurasian cultural interaction. In 138 BCE the Han emperor Wudi (reigned 140–87 BCE) sent Zhang Qian to follow the Yuezhi in an attempt to form an alliance with them against the Xiongnu. Although Zhang Qian was unsuccessful in eliciting support from the now resettled Yuezhi, the information he brought back to the Han court persuaded Wudi to adopt an expansionist policy that brought Han commercial interests into contact for the first time with the traders of Central Asia, Parthia, and eventually Rome.

The Early Kushans

Beginning with Kujula Kadphises (c. 45–85 CE), the early Kushan kings greatly expanded Kushan territory, conquering the Kabul Valley, Kashmir, Gandhara, and much of northwestern India. Numismatic evidence indicates early Roman influence on the dynasty. By the mid-first century CE the Romans were clearly involved in the silk and luxuries trade with India, Central Asia, and China along both the sea routes from Alexandria and the overland Silk Roads through Parthia and Central Asia. Kujula and his successors in turn exerted some Kushan influence on the Han Empire. The Kushans may have exercised direct political and economic control over Hotan (or Khotan) and Kashi (or Kashgar), two major oases towns along the Silk Roads in the Chinese-controlled Tarim Basin, at various times during the first century. Kujula was followed by his son Vima Takto (reigned c. 85–100) and grandson Vima Kadphises (reigned c. 100–127), who in turn was succeeded by his son

Kanishka the Great (reigned c. 127–153), one of the most important rulers in the history of ancient Central Asia.

The Great Kushans

With the advent of Kanishka and his successors, Kushan history entered its most significant phase—that of the “Great Kushans” (c. 127–c. 228). Kanishka and his successors Vasishka, Huvishka, and Vasudeva, presided over a huge, wealthy, multicultural, and relatively peaceful empire in an era often described as the Golden Age of ancient Central Asia. The Great Kushans continued to issue the standard range of copper and gold coins established by Vima Takto. The remarkable weight consistency is in itself evidence of stability and strong central government. The coins reflect a tolerant and broadminded approach to religion, depicting Zoroastrian deities mostly, but also some Greek and Indian divinities.

Although personally devoted to Zoroastrianism, Kanishka is also recognized as a great patron of Buddhism, and the depictions of Buddha on at least one of his gold and several of his copper coin series are amongst the first physical representations of the Buddha. Kanishka is also venerated for having convened an important synod in Kashmir, at which the decision was apparently made to rewrite the Buddhist scriptures from Brahmi and Kharosthi to the more popular and accessible language of Sanskrit. Buddhist tradition suggests that the translations facilitated a great surge in the popularity of Mahayana (“Great Vehicle”) Buddhism, which was then carried across central and eastern Asia by pilgrims using the Silk Roads.

The Great Kushan kings were also patrons of the important art schools established in Gandhara and Mathura. The output of these workshops reflected a cultural synthesis almost unique in art history. The physical representation of the Buddha and bodhisattvas that resulted—a synthesis of Bactrian, Iranian, Indian, and Hellenistic cultural influences—then spread along the trade routes, penetrating India as

far south as Sri Lanka, and traveling through China into Korea, Japan, and Southeast Asia.

The Later Kushans

Following the death of Vasudeva around 228, Kushan history entered a period of decline. The Sasanian ruler Ardashir led his forces from the Plateau of Iran into Kushan territory soon after 226, and the northwestern areas of the former Kushan Empire were incorporated into the Sasanian state of Kushanshar. Sasanian kings emphasized their connection to the Kushans by using Bactrian script to proclaim themselves as *Kushan Shah*, or “King of the Kushans.” Groups of Kushans remained restive until well into the fourth century, however. As late as 367 the Sasanian king Shapur II (309–379) was forced to fight a damaging battle with the Kushans of Balkh in 367 or 368.

In India the rise of powerful monarchical states further undermined Kushan power, although Kushan cultural influence remained pervasive. Even the extensive gold coinage of the Guptas was clearly modeled on the Kushan dinar. An inscription from Allahabad dated around 335, which lists foreign kings who paid tribute to the Guptas, uses Kushan titles to describe the Guptan rulers—“Descendant of the Son of Heaven” and “King of Kings.”

While the disintegration of the Kushan Empire occurred quite quickly, and might have brought to an end the Golden Age of ancient Central Asia, the cultural, political and economic achievements of the Kushans continued to influence their regional successors to perhaps as late as the Islamic conquests (completed early in the eighth century CE). The evidence for the Kushans may be sparse, but is clearly sufficient to demonstrate the significance and cultural legacy of an extraordinary civilization that dominated Central Asia for several centuries and that influenced

the world around it more than any other civilization before the rise of Islam.

Labor Systems, Coercive

Coercive labor is work a person does for another person (or for the state) under compulsion, receiving little or no recompense. The most common forms of coercive labor are slavery, corvée labor, serfdom, and debt peonage. Historically, agricultural societies have tended to rely more on coercive labor than pastoralist and industrial societies.

Coercive labor systems have existed throughout the world and throughout human history, though certain regions of the world and certain periods have been more strongly characterized by them than others. In general terms, agricultural societies brought about the greatest amount of coercion, while pastoralist and industrial societies have usually had minimal coercive labor. The term *coercive labor* is here defined as obligatory work a person does under compulsion for another person of higher status or for the state, receiving little or nothing for the services rendered.

Coercive labor shows up mainly in agricultural societies because that type of society is stable, people do not move around a lot, human labor is essential for the vast majority of tasks, and methods of dominating other human beings are relatively sophisticated. Different levels of coercion have existed, varying over time and place. The most common types of coercive labor are slavery, corvée labor, serfdom, and debt peonage. In the first, human beings are owned and thus made to work with relatively little restriction on the owner. Corvée labor is a system whereby the state forces its people to work for it, though the people are in theory free. Serfs work on the estates of aristocrats, who take a portion of

the serf's harvest and who restrict the serf's ability to move. In debt peonage, an individual is made to work for a landlord because he or she owes the person money, money that usually can never be paid off completely. Corvée labor and slavery are the most ancient types of coercive labor systems and were instituted at the beginning of agricultural societies, about 8,000 years ago. During the earlier hunting-and-gathering phase of human existence and in pastoralist societies, although there were slaves, they were very few because it was difficult to keep them under control.

Corvée and Slavery in the Ancient World

The earliest world civilizations featured both slavery and corvée labor, though in different mixes. Chinese and Egyptian civilizations relied heavily on corvée labor, which from approximately 2700 BCE built the great pyramids and from the Qin dynasty (221–206 BCE) began the Great Wall of China. The Egyptian and Chinese states required peasants who otherwise worked on the land to leave their plots and work on these construction projects. They were usually paid something (often food and lodging), but did not have a choice in whether to work or not. Corvée labor generally was for these large projects, in which the state needed large numbers of people for a limited amount of time and for which most of the work was manual labor that required strong arms and backs rather than skilled labor. Slavery existed only on a small scale in these societies.

Other ancient civilizations featured slavery, such as those in the Mesopotamian region, Persia, and,

Harriet Beecher Stowe's *Uncle Tom's Cabin* helped make slavery a public issue in the United States and Europe. Here a mother implores her son to keep close, lest they be separated at the slave auction.

later, Greece and Rome. Most slaves were gained through warfare, though in all of these societies parents could sell off children or themselves become slaves because of poverty or debt. The vast majority of slaves in these societies were used in agricultural production, working in the olive groves or the wheat fields, though urban slaves were also common. Generally, urban slaves were better off than rural ones, for they lived in the houses of their masters and ate there as well. Some urban slaves were quite well educated, and some elites of Greece and Rome even had slaves as their children's tutors. The possession of urban slaves was a status symbol for many elites.

Slavery in the Muslim World

Slavery remained an important labor system even after the fall of the Roman Empire in the most dynamic portion of the former empire, the lands under Muslim

rule. Slaves came from the margins of Arab civilization, mainly from the Caucasus region and from sub-Saharan Africa. In Islam, slaves who converted to the faith were to be freed, but that rule was mostly ignored after the early years. A free peasantry also existed in the Islamic world, just as in earlier times, but slaves were very important in the urban economy, where people were wealthy enough to own other human beings. Rural slavery also existed, with regional differences. Urban slavery was economically more important than rural slavery in the Arab world.

Muslim societies also used slave soldiers for fighting and maintaining internal control. These slaves were usually from the margins of the Islamic world and, once they had been trained, were especially useful to dynasties that needed soldiers who had no local roots and were absolutely loyal to the ruler. They often led relatively privileged lives, a primary example being the Mamluks, who for a few centuries (1250–1517) ruled the prosperous province of Egypt. The Mamluks were prized because they were trained as superb fighters and owed absolute obedience to their Ottoman masters. By the fifteenth century, however, their loyalties lay more with themselves than the Ottoman Empire. The Ottomans were the most successful in utilizing slaves as soldiers after they established their empire with Anatolia at its core in the fourteenth century. Many of these slaves were Christian boys taken from Ottoman possessions in eastern Europe and trained in the arts of war. They were called Janissaries and were considered some of the best troops of the era.

Serfdom in Japan and Europe

In other regions, another labor system, serfdom, emerged that was partially coercive. Serfdom, associated with feudalism, was common in both western Europe and in Japan in the first millennium of the common era. The reasons for the emergence of serfdom were the same in both regions: extreme political instability in a vacuum of power, in which peasants gave up their lands and their freedom in return for protection from warrior-aristocrats. The serfs' produce provided subsistence to their families and also supported the lords who owned the lands. This

If there is no struggle, there is no progress. Those who profess to favor freedom, and deprecate agitation, are men who want crops without plowing up the ground, they want rain without thunder and lightning. • **Frederick Douglass (1817–1895)**

system declined in western Europe in the 1400s with the advent of urbanization and as the serfs gained the ability to escape or pay the lords for their lands. In Japan, serfdom did not disappear until the nineteenth century. Eastern Europe and Russia experienced a rise in serfdom in the seventeenth century as aristocrats used a strong state to force previously free peasants to become serfs and produce wheat and other grains for sale.

Spread of Forced Labor in the New World

The expansion of Western Europe into the rest of the world beginning with the “discovery” and invasion of the Americas radically changed labor systems in many parts of the world, especially those surrounding the Atlantic Ocean. Coerced labor increased as a result of this expansion. Spanish colonial authorities transformed *corvée* labor systems inherited from New World Indian civilizations into obligatory labor systems that were in all likelihood more onerous than those that existed before the conquest. At first, the conquistadors introduced the *encomienda*, a labor draft required of all conquered Indians. But the Spanish Crown did not want a revival of serfdom (and thus an economic basis for feudalism) on the other side of the Atlantic, so it wrested control of indigenous labor from the first conquerors. In the 1580s Francisco Toledo (1515–1582), the viceroy of the Spanish possessions in South America, revamped the *corvée* labor system completely to provide Indians to work in the silver mines of Potosí, in the high Andes of Bolivia. Indian villagers were supposed to send one-seventh of their able-bodied men to the mines, but the low pay and horrific conditions in the hot and dangerous mine shafts on a mountain more than 4,500 meters above sea level made many Indians flee their villages to avoid being sent. Although silver production went up considerably, the system broke down over the centuries and was abolished with independence in the early nineteenth century.

African slavery, while it had existed for millennia, intensified, especially along coastal regions. The first African slaves came to the Americas with the explorers

and conquistadors. By the seventeenth century Portuguese slave traders, joined by other Europeans, purchased slaves from the interior at trading stations in West Africa and Angola and sent them by way of the “middle passage” across the Atlantic Ocean to the sugar plantations of the Caribbean and northeastern Brazil. To a lesser extent, North American tobacco and, in the late eighteenth and nineteenth centuries, cotton plantations also promoted an export economy based on African slavery.

Approximately 10–12 million Africans were brought to the Americas as slaves. About 40 percent of these ended up in Brazil; roughly another 40 percent were evenly divided between British America and the Spanish colonies. The rest were distributed across the French, Dutch, and Danish colonies. It is estimated that as many 8 million Africans destined for slavery in the Americas died in transit before reaching the New World.

Conditions on plantations, where the vast majority of slaves ended up, were miserable, and most people died within a few years of having set foot in the Americas. Urban slaves, as always, had it somewhat easier. The economically most dynamic areas, such as Brazil and the Caribbean, had the highest mortality, whereas more economically backward areas, such as the region that would become the United States, actually had a population of African heritage that grew rather than diminished without constant imports of human chattel. The eighteenth and early nineteenth centuries saw the height of slavery in the Americas, with the Caribbean islands, Brazil, and the United States being the most important slave regions.

Abolition of Slavery in the Nineteenth Century

By the early nineteenth century slavery was on the wane in the Americas. Antislavery sentiment began to gain ground; by 1807 Great Britain prohibited the slave trade between Africa and its dominions, and the United States followed suit in 1808. The British abolished slavery in their dominions in 1833 and began to fight the slave trade in the rest of the world. Most Spanish American countries abolished

A free race cannot be born of slave mothers. • Margaret Sanger (1879–1966)

slavery by the 1850s. The issue of slavery was most divisive in the United States. The political conflict between the slaveholding South and the industrial North came to a head in 1861 with the U.S. Civil War. President Abraham Lincoln's Emancipation Proclamation of 1862 and the Union victory in 1865 eliminated slavery from North America. In the rest of the hemisphere, although slavery played as large a role as in the United States, abolition was not a bloody affair. Cuba abolished slavery in 1886. Brazil ended the slave trade in 1850 and emancipated all slaves in 1888.

Industrialization, which began to accelerate in the nineteenth century, generally did not favor slave labor. Slaves would see it in their best interest to wreck delicate machinery so that they did not have to work; for this reason it was easier and cheaper to hire free labor that depended on wages to make a living. Also, slaves were not, by and large, economic consumers, and the industrial system needed consumers who earned wages and thus had money to spend on the goods produced by industry.

The end of slavery did not mean that coercive labor disappeared. Other forms, such as debt peonage, took the place of slavery. Debt peonage existed in many regions of the world, especially in the nineteenth and twentieth centuries. Debt peons were to be found laboring on the coffee plantations in Africa and Indonesia, harvesting tea leaves in India, and extracting rubber in the Brazilian Amazon. Debt peonage began to retreat only in the mid-twentieth century, as modern states asserted control and prohibited the exploitation of the rural labor force.

Modern State-Run, Forced-Labor Systems

State-run *corvée* labor reappeared in the twentieth century. The concentration camps established by the Nazis in the 1930s come to mind. Perhaps the largest numbers of people involved in nonvoluntary labor in the past century were those put to work in Communist states such as the Soviet Union and the People's Republic of China. The Stalinist industrialization policies in the 1930s and the Great Leap Forward,

an attempt at universal small-scale industrialization in China in the 1950s and 1960s, led to great misery and the deaths of tens of millions of people. In addition, Communist countries maintained large prison systems and put prisoners to work in harsh environments without much regard for their survival.

During World War II, the Japanese Army forced Korean, Chinese, and Filipino women and some Japanese prostitutes to serve as sexual slaves, euphemistically called "comfort women," for Japanese soldiers. This was a type of state-run coerced labor that also existed in several armies in the former Yugoslavia and in some states in Africa during the civil wars that plagued these regions in the late twentieth century.

World Systems and Forced Labor

Why and how do coercive labor systems exist? The world economy model outlined by the sociologist Immanuel Wallerstein offers one answer. In this model, Wallerstein suggests that coercive labor systems, at least since the 1500s, are the result of a world capitalist system imposed by western European economic expansion. In particular, regions dominated politically or economically by European powers, such as the Western Hemisphere and Africa, evolved coercive labor systems. These "peripheral" regions (so called because they are peripheral to the dominating powers) exported primarily raw materials such as silver, sugar, and cotton. Given that they only exported cheap raw materials but needed to pay for expensive European-made manufactured goods, the elites in the peripheries had to exploit native labor or import slaves to lower the production costs of the goods they exported. Otherwise, the elites in the peripheries would be unable to sustain their lifestyles. This model, according to Wallerstein, worked until the twentieth century, when coercive labor practices became milder but did not vanish.

Coerced Labor Today

Coerced labor continues to exist today, though it appears that mainly women and children, rather than

grown men, are targeted. Children in the Middle East and South Asia are forced to work in sweatshops making items such as Oriental rugs. Criminal gangs lure young women from the former Soviet Union and Eastern Europe to the West with promises of good jobs, and then force them to work as prostitutes when they cannot pay back their travel expenses.

Another type of forced labor that is common, especially in areas where there are civil conflicts, is the use of child soldiers. Children as young as ten (though most are between the ages of 15 and 18) have been forced into militias in places such as Sierra Leone and Colombia. They also serve as lookouts and porters. About a third of the child soldiers are girls, who are frequently raped and given as “wives” to adult soldiers. Thus, coerced labor is still with us, although human rights agencies and many governments are trying to eliminate this exploitation.

Labor Union Movements

Labor (or trade) unions, formed by workers who join forces to oppose exploitation on the job—whether in factories or fields—use the power of collective bargaining to achieve certain employment and working rights and entitlements that relate to fair pay, safe working conditions, and general worker welfare.

The first labor unions were formed by working men and women in the mills, workshops, and small factories of late-eighteenth-century England to protect themselves against low wages, long hours, and poor working conditions. In part, growing out of Europe's medieval craft guilds, which provided social and material benefits for their members, early unions of weavers, bricklayers, and cordwainers (shoemakers) established models and methods of labor organization that were adopted and further refined as industrialization spurred a dramatic increase in wage-earning labor in the nineteenth century. Over the next century, labor unions in Europe and the United States would expand beyond manufacturing to include miners and agrarian workers throughout those and other areas of the world. Today, tens of millions of men and women—albeit still a minority of all workers internationally—are organized into labor unions.

At least in part, the development of labor unions was linked and in response to the growth of industrial society and the rise of capitalism as an economic system. Beginning in the late 1400s, a centuries-long demographic shift from the countryside to cities took place that saw tens of millions of peasants and subsistence farmers in Eurasia, Africa, and the Americas forced off their land to become indentured servants, tenant farmers, or agrarian workers. Meanwhile,

millions of men, women, and children—increasingly from western and central Africa—were enslaved. As commerce expanded and the number and size of existing cities grew, so did the number of men, women, and children brought into the paid workforce.

Simultaneously, movements for political and economic reform in the nineteenth century would help abolish slavery in the Atlantic world and then later in the Indian Ocean world. As with slavery, serfdom and other forms of quasi-forced and forced labor were made illegal throughout most of the world by the twentieth century. With agriculture becoming increasingly mechanized in the early twentieth century, the ranks of urban labor swelled. Unable to compete against large-scale agricultural production, growing numbers of small land-owning rural workers joined those whose lands had been stripped from them by force or insurmountable debt and migrated to cities seeking work.

Under the employ of shop owners who sought to maximize their profits by depressing wages, urban workers—both skilled and unskilled—helped grow both international production and the global market by transforming raw materials such as cotton, sugarcane, copper, and lumber that had been harvested, mined, or felled by rural workers and slaves into consumer goods, construction materials, and finished luxury items. Workers banded together, calling for higher wages and better working conditions; eventually they demanded insurance against illness, accidents, and work-related disabilities—benefits offered by mutual aid societies often tied to religious bodies or fraternal organizations. Labor unions would therefore contain elements of both early craft guilds and mutual aid societies.

This chart shows the causes of strikes and their rates of success in the United States during the closing decades of the nineteenth century.

Differing substantially in their ideologies, tactics, and degrees of influence, labor unions have assumed a variety of forms over the past two centuries. Some have called for a reorganization of society based on cooperative work, while others have sought only the material improvement of their members. While the demands of labor unions have changed over time, depending on local circumstances, their basic purpose remains the same: protecting the interests of their members by means of collective bargaining. In time, unions would also engage in political action and in some cases, militant action. Along with the right to organize, today's unions largely seek contractual agreements with employers that guarantee workers specific wages, safe working conditions, and the right to arbitration, health care, and retirement benefits. On the whole, union members in most industrialized countries enjoy more rights, higher wages, and better working conditions than their counterparts in the less industrialized parts of the world, whose governments have yet to either enact into law or enforce standards that relatively more privileged workers have come to take for granted.

Irrespective of location, the bargaining power of labor unions ultimately rests on their members' ability to collectively withhold their work and to exercise their organization's financial, legal, and electoral voting strength. Since the late eighteenth century, workers have exerted their power by carrying out, or threatening to carry out, strikes, boycotts of goods, hold demonstrations, picket lines, petition governments, file class-action law suits, mobilize voters, fund political parties or electoral campaigns, and, in some cases, engage in armed struggle. Labor unions have also served as sources for community support and development, providing public forums as well as

private spaces for social gatherings, educating their members, disseminating news, and training new leadership.

The appeal of union membership for workers, whether guided by self-interest or a sense of responsibility to their fellow workers and society at large, has been countered by employers threatening to fire or punish employees who join a union, or using physical violence or legal measures—backed by state force—to keep unions from growing in strength. During the nineteenth and early twentieth centuries, courts in the United States frequently issued injunctions to halt strikes. In Peru, private industries have hired armed guards to attack striking workers—a practice seen in many parts of the world. At certain periods in South Africa, as elsewhere, labor leaders have been imprisoned for mobilizing workers.

Europe

Europe's labor unions have gained a number of lasting concessions since the nineteenth century, making the continent's workforce among the most privileged in the world today. Still, every gain made by these workers—from the right to organize, to paid maternity leave—came as the result of protracted labor struggle. During the second half of the nineteenth century, and only after engaging in decades of boycotts, strikes, work slowdowns, and physical violence, European labor unions secured minimal legal protections. In France, the bourgeoisie-dominated revolutionary government of the late eighteenth century enacted the Le Chapelier law to make workers' coalitions illegal, while Britain's parliament reinforced existing laws against organized workers through the Combination Acts of 1799 and 1800. Nevertheless, by the

1820s recognizable European labor movements had emerged, accompanying the growing importance of coal production (over steam) and the concentration of large urban populations.

In 1868, Napoleon III, who had used the military to quell striking workers, finally assented to the formation of labor associations. Fourteen years later, France's Third Republic fully legalized unions. In turn, Britain's Parliament legalized labor unions in 1871; four years later they granted British workers the right to picket. Workers in Germany were extended the right to organize unions with relatively less struggle than their British and French counterparts, but not until the 1890s. Over the course of the nineteenth century, tens of thousands of workers were killed or seriously injured, whether on the job, because of hazardous working conditions, or in the course of labor agitation. Thousands more were beaten or imprisoned for union organizing and making demands by stopping or temporarily interrupting production.

The politicization of labor unions in the mid-nineteenth century produced incendiary results—most notably, the revolutions of 1848. Such ferment, whether in the factories or fields of Europe, served as the backdrop for later reforms that attempted to appease workers, even as governments and private enterprise shored up their forces to repress dissent. Despite legal and illegal measures to thwart European labor movements, union-led revolts continued.

One of the most dramatic instances of organized European workers asserting their political power took place in 1871, when French workers, together with anarchists, socialists, and communists, temporarily formed their own revolutionary government, the Paris Commune. In the spring of that year, workers seized control of the capital and quickly enacted a series of laws establishing debt relief and shorter working days. While the Communards, as they were called, were defeated within two months by loyalist French and Prussian military forces, their brief takeover served as a reminder of the power of organized labor. As increasing numbers of adult male workers gained the franchise in the latter half of the nineteenth century, organized labor across Europe began to exercise

greater influence in determining which candidates and parties best served their interests.

By the end of the nineteenth century, efforts to organize unions extended to the unskilled labor force. Industrial labor unions comprising workers across entire industries regardless of skill (as opposed to trade unions that had been restricted to skilled workers) were formed. As expected, industrial unions, like trade unions, were met with bitter opposition from employers and the state. In the decade preceding World War I, Europe saw a rash of strikes as labor unions fought to keep wages in line with rising inflation; strikes could last for months, entailing extraordinary hardship for working-class communities.

Despite the many obstacles, labor unions in Europe continued to grow. By 1910, approximately three million workers were organized in Britain; two million in Germany; and one million in France. Still, the vast majority of workers in Europe remained unorganized. As the century wore on, industrialization steadily supplanted other forms of production and the labor force came to be dominated by industrial workers; as citizens and soldiers, many also bore the brunt of World Wars I and II. The first of these wars witnessed the birth of Soviet Communism, and with it a "workers' state" (deformed under Joseph Stalin). The second saw the defeat of European and Japanese fascism.

With the Bolshevik Revolution of 1917 and the subsequent formation of the Union of Soviet Socialist Republics, Russia's trade unions were incorporated into the structure of government. Meanwhile, socialist countries in Europe, including those in Scandinavia, had been transformed into constitutional monarchies that instituted sweeping social and economic reforms. As the Soviet Union extended its sphere of influence in Eastern Europe, trade unionism came to dominate the region.

During the 1930s, and at the other end of the political spectrum, the fascist government of Italy attempted to contain its labor movements by sponsoring its own trade unions. In 1933, Germany's fascist regime destroyed what had been Europe's best organized trade union movement, and then attempted

Women need not always keep their mouths shut and their wombs open. • **Emma Goldman (1869–1940)**

to bring its entire labor force under the control of the Nazi party. But following the defeat of fascism in World War II, and their “corporate” attempts to control labor, those countries’ union movements were revived.

By the second half of the twentieth century, many of the demands made by industrial and trade unions in Europe had been translated into government policy, benefiting the broader population—beyond organized workers. The adoption of universal health care programs was among the most important of government reforms enacted under pressure from labor unions in Europe.

United States

Organized labor in the United States succeeded in gaining a number of critical concessions: a minimum wage, reduced working hours, child labor laws, disability insurance, and retirement benefits. But the incalculable social, political, and economic impact of slavery in the United States (which produced material surpluses for the accelerated growth of capitalism internationally), combined with large-scale European immigration in the late nineteenth and early twentieth centuries, led to multiple fractures within the skilled and unskilled labor force. Workers were divided, and often pitted against one another, on the basis of race, ethnicity, and gender.

The first labor unions in the United States appeared in the early nineteenth century, growing directly out of the established guilds—blacksmiths, carpenters, cabinetmakers, and cobblers. By the 1820s, various trade unions were calling for the reduction of the work day from twelve to ten hours. As the use of steam engines along the Atlantic seaboard and internal waterways gave rise to new factory systems, paralleling the development of factories in England, labor unions in the United States sought to join together in citywide federations. In 1866 these federations formed the nationwide National Labor Union (NLU), which succeeded in persuading Congress to pass an eight-hour workday for federal workers. But by the early 1870s the NLU had unraveled.

Labor agitation resurfaced with unprecedented force later in the decade. In 1877, a national railroad strike paralyzed the nation’s transportation system when workers in Martinsburg, West Virginia began a strike that quickly spread to St. Louis and Chicago, to Baltimore and New York, eventually reaching Pittsburgh, where discontent over reduced wages had originated. In several places workers resorted to violence, destroying railway lines to protest low wages and ill treatment. The national strike, known as “The Great Railroad Strike of 1877,” attracted widespread public sympathy and was only suppressed through the force of state militias.

Over the following decade, the Knights of Labor, a union formed by Philadelphia garment cutters in 1869, became labor’s preeminent organization. Expanding nationally under the leadership of Terrence V. Powderly, the Knights organized skilled and unskilled workers, men and women, blacks and whites. By 1886, the organization boasted a diverse membership of 750,000, which included urban and rural workers, although the southern branch had increasingly become all-black as southern white laborers refused to participate in interracial locals. The all-black membership soon joined the ranks of other African American workers in the Cooperative Workers of America and the Colored Farmers Alliance, whose combined membership grew to over one million strong, forming the largest movement of black agrarian workers and sharecroppers in U.S. history. In the coming years many within the organized rural black labor movement—Black Populism—joined white farmers and laborers to establish the People’s Party, which advocated on behalf of labor and agrarian interests.

In the 1880s, as the Knights of Labor became a national force demanding an eight-hour workday, both its leaders and the rank and file were targeted for retribution. On 4 May 1886, the Knights held a mass rally to protest police brutality: the day before, striking employees at the McCormick Harvester Company had been severely beaten; one was killed during a clash with the police. Following the mass rally, eight anarchists were accused of throwing a bomb that killed seven policemen, while the police were accused of

The Brotherhood of Sleeping Car Porters was the first recognized black labor union.

indiscriminately shooting into the crowd, beating up dozens of workers, and killing four in the process. The incident became known as the Haymarket Massacre, for which the Knights were unjustly blamed. A precipitous decline in the union's northern, and mostly white membership followed soon thereafter.

The year 1886 also saw the formation of the American Federation of Labor (AFL), led by Samuel Gompers, a cigar roller. The AFL would soon assume the preeminent position that had been occupied by the Knights of Labor. Unlike the Knights, however, which organized across industries, the AFL concentrated on organizing craft unions of highly skilled workers. Opposed to any alliances with radical political parties, Gompers emphasized economic rather than broad ideological goals. Under his stewardship, the AFL ushered in the modern era of organized labor, maintaining emergency funds to help members during strikes, and employing paid organizers to sign up members in nonunion shops. But the exclusive posture of the AFL precipitated a serious rift within the U.S. labor movement, its ranks swelling with immigrant and mostly unskilled workers. In the long run, the organization's decision to focus on the economic interests of the nation's most skilled workers—a decision fueled by racism and growing anti-immigrant

sentiment—debilitated the potential for a unified labor union movement.

Other labor unions competed with the AFL for membership. In 1894 the American Railroad Union under the leadership of Eugene V. Debs, a leading socialist, organized a strike at the Pullman manufacturing plant near Chicago and called for a boycott by the men who handled the company's sleeping cars for the nation's railroads. Within a week, over 125,000 railroad workers across the nation went on a sympathy strike. At the request of the Illinois governor, the U.S. president Grover Cleveland intervened, moving in federal troops to break the strike. Under the threat of military intervention and a broad injunction, the sympathy strike was ended. The Pullman strikers were defeated, many of whom were blacklisted for their involvement.

The opening of the new century witnessed a flurry of strikes. In 1902, coal miners in northeastern Pennsylvania called for a strike. Under the leadership of John L. Lewis, their union, the United Mine Workers (UMW), mobilized some 100,000 coal miners who shut down the coal mines in which they worked. When the owners of the mines turned down a UMW proposal for arbitration, President Theodore Roosevelt, like his predecessor, intervened. This time

the president appointed a commission for mediation and arbitration. Five months later, the commission awarded the workers a 10 percent increase in wages and a shortened workday. But it denied the union's demand for formal recognition, which was a precondition for arbitration; in its absence, workers faced loss of wages, and maybe even starvation.

It sometimes took an industrial catastrophe to spur the enactment of workplace safety regulations. In 1908, twenty thousand women garment workers in New York and Philadelphia walked off their jobs to protest harsh working conditions. But it was only after 146 young female workers died when a fire broke out at the Triangle Shirtwaist Company on New York's Lower East Side in 1911 that the government finally acted to remedy hazardous working conditions in New York factories. Many of the women at the Triangle Shirtwaist Company had plunged to their deaths, forced to jump out of windows when the fire broke out because the owners had insisted on keeping the doors of the building locked from the outside to prevent "loss of goods." An outraged public helped pave the way for the enactment of industrial safety reforms, beginning with the targeting of sweatshop conditions in the garment industry.

Favorable public sentiment played an important role in the growth of labor unions. In 1912, the Industrial Workers of the World, a militant multiracial union, led a strike of fifty thousand workers in the textile mills of Lawrence, Massachusetts. When striking women and their children were attacked by police, a large public protest ensued; the textile workers' pay was eventually restored and then increased. An important victory for the broader U.S. labor movement was won two years after the Lawrence strike when Congress passed the Clayton Act, which legalized strikes, boycotts, and peaceful picketing. Referred to as the "Magna Carta" for labor, the Clayton Act also limited the use of injunctions to halt strike actions. But another generation would pass before unions were fully recognized.

During the Great Depression, when labor agitation reached new heights, the federal government finally conceded the right of unions to legal recognition.

Such labor agitation included pressure by the International Ladies Garment Workers Union, whose membership was predominantly Jewish and Italian immigrants. Pressure also came from A. Philip Randolph's black-led Brotherhood of Sleeping Car Porters. Beyond government recognition, other important demands gained during the 1930s by labor unions were the long-fought-for minimum wage, the reduction of working hours, child labor laws, and welfare programs. The rising tide of labor union agitation in that decade culminated in the formation of the Congress of Industrial Organizations (CIO), which brought millions of unskilled workers from the rubber, steel, and other basic industries under a single umbrella.

In 1935, Congress passed the Social Security Act and the Wagner Labor Relations Act, which created the National Labor Relations Board. While labor unions thereby gained increased power, the federal government's concessions set the stage for the co-optation of the movement and its leadership under President Franklin D. Roosevelt's New Deal.

The advent of World War II saw an increase in union organizing, which was accompanied by a deepening alliance of organized labor and the Democratic Party. The abandonment of the U.S. labor movement's political independence (through the support of pro-labor third parties in the electoral arena), ostensibly to unify the country in the face of fascist forces overseas, left the movement vulnerable to attacks once the war was over. Upon the conclusion of the war a purge of left-wing union leaders took place, led by Senator Joseph McCarthy. The era saw the enactment of the Taft-Hartley Act, which made "closed shops" (where only union members were permitted to work) illegal and outlawed the secondary boycott (whereby union members draw the sympathy of others to boycott the goods of a given company). The legislation also allowed the states to pass right-to-work laws, thereby placing further obstacles in the way of union organizing.

With radical leadership effectively barred from union movement, the AFL and CIO merged in 1955. One consequence was a threefold increase in weekly earnings for workers in manufacturing by 1970; less

The most heroic word in all languages is revolution. • **Eugene Debs (1855–1926)**

positive, however, was the severing of the low-wage secondary labor market from organized labor. Union organizing has never extended beyond one-third of the U.S. labor force; as a result the most highly skilled workers have come to benefit from the advantages of organized labor, while the distance between them and other workers continues to grow.

Latin America, Africa, Asia

Like their counterparts in the most industrialized regions of the world—Australasia, Europe, the United States, Canada, and Japan—skilled urban workers in Latin America, Africa, and certain areas of Asia have made significant gains over rural and unskilled workers. The most important of the union labor movements on these continents were affiliated with communist or socialist-led political forces, most notably the People's Republic of China, founded in 1949.

The Chinese Communist revolution, like its predecessor in the Soviet Union, attempted to place agrarian production under state control and to bring about large-scale industrialization over a much shorter period of time than the Western capitalist countries had experienced. Social, political, and economic advancements notwithstanding, for significant segments of China's population, the accelerated pace of industrialization produced significant social disruption, uneven development, and a reworking of power relations that left hundreds of millions of peasants, previously under the authority of overlords, now subservient to local party officials who were inclined to practice the same kinds of oppressive behavior exhibited by the landed gentry they replaced.

In Latin America, working-class political parties worked closely with the unions to support their labor movements. In the first decade of the twentieth century Argentina's anarchists assumed leadership in union organizations, promoting anti-government policies that provoked the government to become increasingly repressive of organized labor. Labor leaders were deported and waves of general strikes were met with state-sanctioned violence. To undercut radicalism and build support for their regimes among the growing indigenous and mestizo work force, governments

throughout Latin America enacted legislation to provide at least a minimum level of social welfare for its citizens. This approach was carried out first in Uruguay at the turn of the twentieth century, followed by Mexico in the 1920s, and Brazil in the 1930s. Many labor unions in Latin America went underground while working to support pro-labor political parties and their candidates—as was the case in Bolivia with the Movimiento Nacionalista Revolucionario, a party closely tied to the miner's federation. Today, a minority of workers in Latin America, concentrated in its major cities, are organized into labor unions.

The economies of many African nations continue to rely on subsistence farming, with relatively little industrialization. A continent rich in minerals, the mining industry is among Africa's principal sources of industrial labor; it is also the industry with the most viable unions. Following independence from European colonialism, many industries on the continent were placed under state control. But many industries also remained under de facto European corporate control or majority ownership. In 1973, however, a wave of strikes in Durban, South Africa, marked a new militancy among African labor unions not seen since the formation of the anarchist-led Industrial Workers of Africa, the first union of black workers in South Africa. The union influenced the African National Congress in a more radical direction, which led, ultimately, to the overthrow of the apartheid regime in 1994. Over the course of the second half of the twentieth century, legislation was passed in South Africa to regularize industrial action, giving new legitimacy to union organizing. Despite such legislation, and coupled with the end of apartheid, like workers in the more industrialized regions of the world, most of South Africa's labor force remains unorganized.

As in the case of South Africa, a militant workers' movement in Egypt helped to undermine British colonial presence as well as Egypt's monarchy. Between 1947 and 1953, a rapid growth in the textile, tobacco, and sugar industries saw the doubling of Egyptian union membership. The International Confederation of Arab Trade Unions, founded in 1956, would, in turn, shape the Egyptian government's commitment to organized labor in the Arabic-speaking region

while integrating the nation's active trade unions into the state system.

Outlook

A history of labor union movements suggests certain common threads as much as it illuminates the diversity of organized labor around the world. While most workers have not been organized into labor unions (in the U.S. only about 15 percent of workers are currently organized; down from 30 percent during the 1950s), and while there is now a greater disparity in wealth within nations around the world than had existed at the beginning of the nineteenth century, certain segments of the international labor force have won legal rights that offer them some protection against the exploitative tendencies and practices of industrial capitalism.

Language

As humans evolved so did our ability to speak, but how and when language began remains a mystery. Linguists who study the nature of language see patterns in related language families—some expanded while others died out. Although languages were never fixed, several universal aspects of their use allowed our ancestors to express ideas about invisible spirits and gods; to formulate rules; to plan ahead; and, when plans failed, to talk things over.

Language became universal among humans because the advantages of its use were so great that only those who learned to use it survived. How and when human language began remains unknown. Changes in the shape of our throats and voice box were necessary before the full range of sounds used in human languages could be voiced, and only bones survive from when those changes in our soft tissues occurred. New connections in human brains were also necessary, for children's brains are genetically ready-wired to learn a language, as anyone who has watched a small child effortlessly learn to speak will realize; but that aptitude disappears among older persons, who use entirely different brain cells when trying to learn a second language.

If we ask what advantages the use of language brought to our ancestors, the first and most obvious answer is that resort to words permitted larger numbers of persons to cooperate more predictably and efficiently than ever before. That in turn made larger bands of hunters and gatherers able to defend their hunting grounds more effectively than any and all neighbors who had not mastered speech, so soon only those who talked survived.

But languages were never fixed. Always they conveyed an unstable pattern of meanings to humans through shifting sounds uttered according to grammatical order. Multiple, mutually unintelligible languages presumably took shape very quickly among different groups, and never stopped changing. The process continues today: some languages expand, others die out, and all of them alter, partly deliberately by the invention of new words for new things, or by borrowing from another language. But often, too, unconsciously, grammar, accents, and intonation alter among local speakers and sometimes accumulate locally until, with sufficient isolation, a local dialect turns into a new and different language.

Linguists study the nature of language and how it evolved. They have discerned families of related languages that spread widely in times past and are now used by millions of speakers. But thousands of other languages exist even today, some only spoken by a few hundred persons and likely to disappear entirely as contacts with the outside world multiply, and compel these small groups to deal with outsiders in a language other than their own.

Talking about Spirits and Gods

But amidst all the changes, some aspects of language remained worldwide, and they are worth noting. One of the most fundamental was the way our ancestors used language to expand the human experience to include a world of invisible spirits whose power was such that managing relations with spirits (later with gods) became a critical growing point for human society as a whole.

The Naxi people of Yunnan Province, China, possess the only extant pictographic writing system in the world. The use of Naxi Dongba script is restricted to priests and shamans, who read it when presiding over religious ceremonies and rituals.
Library of Congress.

The initial notion of an invisible spirit almost certainly derived from noticing human breath and observing the fact that when breath stopped death ensued. Though invisible, breath obviously mattered. It kept us alive, allowed us to move, talk, and think, and was our “spirit.” Wondering about how breath could do so much, coming in and out of our bodies unseen for a lifetime and then departing, suggested that other important aspects of human experience, especially dreams, trance, fevers, and illnesses, might result when our breath or some other invisible spirit—either friendly or hostile—invaded or departed from our bodies. From this understanding it was easy to assume that everything that moved—especially animals, air, water, and storms, together with sun, moon, planets, and stars—did so because spirits visited them too. It seemed, in short, that the whole world was also inhabited by invisible spirits, interacting with one another and with all the different bodies they chose to inhabit or abandon. It followed that all human hopes and fears depended on how the world of spirits behaved by either helping or hindering us at every turn.

This worldview took shape very early; perhaps soon after language itself came on stream. When human hunters spread around the inhabited Earth, beginning about 40,000 years ago, they carried these ideas with them. Moreover, most or all hunting bands relied on experts for dealing with the spirits. They became the first specialists, since assuring good relations with the spirits through rituals, prayers and offerings was obviously necessary to assure success for every human undertaking. Modern anthropologists call this world view “animism,” and it still lurks in our speech when we speak of “inspiration.”

When writing was invented, language and religion attained still stronger, and more lasting, hold on human minds. Prophets, teachers and law givers, by

writing their messages down, created texts that were believed to be directly inspired by God, or so wise and persuasive that later generations ought reverently to obey them. But later religions and most philosophies preserved a central idea of powerful invisible spirits (and later of a single omnipotent God) who demanded obedience and punished those who disobeyed.

Religious ideas were critical for the elaboration of early civilizations, for after agricultural villages supplanted hunting and gathering in a few unusually fertile regions, what persuaded ordinary farmers to part with a portion of their harvest was the harsh reality that they needed protection against natural disasters and human raiders. In the land of Sumer (modern Iraq), where the first cities arose, priests who specialized in serving invisible gods argued that to assure a god’s presence and good will it was necessary to build a magnificent temple, complete with a cult statue to live in, and to then persuade the god stay by giving him or her daily offerings of food, music, incense, and dance. Only when richly and reverently attended could the god be counted on to grant the priests prayers on behalf of the population at large.

Splendid and rare furnishings for larger and larger temples were needed to attract and retain a suitably powerful divine resident in each city, so priests collected a large share of the harvests to pay for rarities from afar as well as for their own upkeep. This was a recipe for resorting to long-distance trade employing donkey caravans overland and ships along the coasts of the Persian Gulf and Indian Ocean. Before long the temples of Sumer, like spiders at the center of their webs, consumed indefinite quantities of precious imported goods and used extra grain to feed large numbers of spinners and weavers, who manufactured woolen cloth for export to distant places in exchange.

A new scale of human communication and interaction ensued, tending to expand the reach of cities and of other city-based specialists—artisans, merchants, and warriors—across hundreds of miles. Other early civilizations also accorded a leading role to priests who served different gods, with rituals and theologies as diverse as the languages they spoke. But over and over again, when cities and temples became conspicuously wealthy, armed raiders from marginal lands tried to seize that wealth. Military leaders thereupon organized armies to protect everyone from raids, and eventually professional warriors overshadowed priests as the rulers of civilized peoples. Yet religious ideas and leaders always remained powerful; and belief in the power of an invisible God who controls human affairs remains profoundly influential today in monotheistic societies.

Regulating Behavior / Planning Ahead

A second and no less significant effect of language among our ancestors was to regulate everyday behavior by putting what everyone should do in all ordinary situations into words. When such rules survived the test of time, they became customary; obedience became almost universal, easing personal decisions and making interpersonal encounters more nearly predictable. Above all, cooperation became more efficient when customary codes of conduct, learned in childhood, minimized frictions, stabilized human life (insofar as that was ever possible), and guaranteed continuity generation after generation in most circumstances.

But continuity never banished change, for language also had a contrary effect of provoking new behavior whenever human expectations were disappointed. We can be sure that disappointments arose long before language developed among our ancestors; and humans and proto-humans had always been more apt to change their behavior than less intelligent species. But when language made use of tenses—was, is, will be—and other devices to describe the stream of time, the range of human consciousness widened enormously—so much so that we really cannot know what it was like to live in a sensory present without

words connecting what our senses apprehend each moment with past and future happenings. Animals live that way, and most certainly do have memories; but they may not be able to conceive of the future as we do with its uncertainties, risks and, rewards.

It seems sure, however, that when time distinctions took hold of human consciousness two things happened. First of all, it became possible to plan ahead, and by talking together in advance to agree on what each person should do to ensure success in the hunt, or whatever other task they set out to accomplish. Smoother and more precise cooperation must have resulted, together with more frequent success. This was, in all probability, by far the greatest advantage language initially brought to our ancestors.

But success was never total and when plans failed, people were almost compelled to ask, “Why”? And by talking things over they might agree to do something different next time. Prayer to appease angry spirits, especially those of game animals, may have been the most common remedy they could think of. That would seldom make any difference, though sometimes might make individuals braver or more vigorous in pursuit of a kill. But occasionally different tactics, different tools, or some other innovation brought success more dependably, and in such cases one can be sure the new ways quickly became the norm and spread among neighbors whenever imitation was feasible.

The fact that about 40,000 years ago, styles of shaping stone tools began to change in Europe far more quickly than before perhaps signals the effect of language on tool making. At any rate, it is the earliest known example of accelerating technological change which became obvious and swifter in subsequent ages and has recently increased our impact on other forms of life, and on the whole ecosystem, in ways that may not be sustainable much longer.

Yet language may also allow us to talk things over as before and alter our behavior soon enough to survive by minimizing disastrous effects of the recent pollution of our ecosystem. That is an optimistic view, for we can also imagine the possibility of life-destroying catastrophe—atomic warheads, global crop failure, or lethal disease—that might end our career on Earth with a bang or, alternatively, with a whimper.

Either way, our future, like our past, will be shaped through the use of language, thanks to actions inspired by words used to create agreed-upon meanings among us.

Language, Classification of

The classification of languages, both those in use and those no longer spoken (but existing in the written record), depends on principles of linguistics that study languages in terms of their structure, their geographic distribution in the world, and their genetic relationship in language families.

The classification of human languages is a scientific activity that aims at grouping the approximately six thousand living languages of humanity (and the several hundred known languages that are no longer spoken but that left written records, some of them up to five thousand years old) into historically meaningful subsets. Throughout the history of linguistics—the scientific study of language—various principles have been used to arrive at such subsets, the three most important of which are the principles of typology, the principle of linguistic areas, and the principle of genetic relationship.

Linguistic Typology

Linguistic typology studies the possible and actual variation of human languages in terms of their structure. Thus, languages may differ in terms of the number and type of sounds (phonemes) they use. Some, for example, may have a very high number of consonants, as is true for most languages of the Caucasus region; others may have very few of them, as is the case in many Polynesian languages. The structure of words may differ widely; some languages use few if any form changes to alter the meaning of words (morphology), as is the case in Vietnamese and many other languages of Southeast Asia, while other languages

(many Native American languages, for example) have highly complex morphological systems. Almost any structural feature of languages may be and is used by typologists to compare languages and to group them into sets of languages that behave in a similar way.

The study of the typological variation of human languages reached a first peak in the early nineteenth century. The assumption that structural/typological similarity/uniformity of languages is also indicative of common descent (“relationship”) was gradually abandoned, however, when it became clear that languages may lose or acquire many structural features (previously thought to be quite invariant in the course of time). Thus, for example, a language may develop a systematic contrast of tone height to distinguish meanings (it may become a “tone language,” like Chinese), or, on the other hand, it may lose this feature (as, in fact, any other linguistic feature describable in typological terms). While language typology, after a certain period of comparative neglect, developed again (since the 1960s, driven by the seminal works of J. H. Greenberg), into one of the major and most successful subdisciplines of linguistics, it is no longer regarded as a primary tool for the detection of the (possible) common origin of languages.

Areal Linguistics

Areal linguistics studies languages from the viewpoint of their geographical (areal) distribution on the planet. While phenomena like this have of course been well known to students of language for centuries, areal linguistics as the systematic study of language interaction gained considerable momentum with the work of K. Sandfeld in the 1930s, which

drew particular attention to the striking similarities of many languages of the Balkans, which could only be explained as due to prolonged intensive contact between speakers of these languages (Greek, Serbo-Croat, Albanian, Rumanian) over many centuries. Rather than merely, and trivially, stating their locations, areal linguistics aims at elucidating the way languages spoken in adjacent regions influence each other. It is well known that words often travel from language to language (in English these loanwords include *beef* from French, *gestalt* from German, *habitat* from Latin, *taboo* from Polynesian, and *tipi* from Siouan), but languages also influence each other in terms of their structure as well. If the contact between two or more languages in a given area extends over a considerable period of time—generations or even centuries—it is often observed that structural traits of these languages converge, often to a considerable degree. In some cases a (politically or culturally) dominant language “attracts” other languages in its geographical scope, whereas in other cases languages in a given area (which may be continent sized) show a large degree of common structural traits that are best explained by areal convergence, but without a single discernable dominant language that can be held responsible for this picture. Well-studied areas of structural convergence of languages (for which the German term *Sprachbund*, literally “league of languages,” is widely used) are the Balkans, the Indian subcontinent, the American Northwest, the Caucasus, and New Guinea, but more generally such phenomena are observable across the planet.

In some cases, the study of the areal interaction of languages may, if used with due caution, reveal information about historical processes that took place sometimes even before the communities in question came into the scope of written history. The role of Scandinavian and, later, Norman French people in the history of England is well known and documented, and these periods of historical contacts left their footprint in the English language, but in certain cases language alone points scholars to contacts that may have taken place in early history. For example, certain traits of the Russian language betray the fact

that large areas of what is now central European Russia were once populated by tribes speaking languages akin to Finnish before the expansion of East Slavic/Russian to the east of Moscow (fifteenth–sixteenth centuries CE). Later those tribes were assimilated or driven out of those territories to survive only at their fringes. Another example worth mentioning is the presence in Zulu (and certain other languages of the Bantu language family in southern Africa) of “click” sounds that are characteristic of one or more early variant(s) of the so-called Bushman (Khoisan) languages, which today are spoken quite far away from Zulu territory, but which must have been present there in times well before our historical records for this region begin.

Genetic Linguistics

The third method of grouping the welter of human languages into meaningful subsets is that of genetic or historical comparative linguistics, which attempts to identify language families (groups of languages) that share a common ancestor language, which is usually no longer spoken and more often than not is not even attested in any written record. While areal and typological linguistics are sometimes able to lead researchers to insights into the general history of some regions of the world, genetic linguistics makes historical information a primary concern. People have been grouping “similar” languages into “families” for centuries, thus, for example, the basic unity of the Romance languages (as descendants of Latin) or that of the Semitic languages have been commonplace since the Middle Ages. No traveling speaker of Russian could ever fail to notice that, for instance, Polish is more “similar” to Russian than it is to German and, therefore, a prescientific notion of Slavic as a family could emerge long before the advent of linguistic methods. We may call such families, the unity of which is usually discernable for the untrained observer, or, in other words, evident on mere inspection, “trivial” language families. It was not before the turn of the end of the eighteenth century CE that language scholarship developed methods which allowed

the detection of “deeper,” “non-trivial” relationships between languages.

In many well-known cases, the genetic classification of languages alone was able to inform scholarship of sometimes large-scale prehistoric movements of people, which would have gone unrecognized otherwise. Some cases were quite surprising: the detection of the Indo-European family of languages at the end of the eighteenth century revealed the at the time unexpected fact that most languages of Europe (indeed, all but Finnish, Estonian, Hungarian and a few others related to them—the Uralic languages—and Basque, which does not fit in any language family) are demonstrably related to many languages of Asia, including Armenian, the Iranian languages, and Sanskrit and its relatives).

Genetic relationship of languages implies that the ancestors of the peoples using the languages in historical times must share a greater deal of their early history than other sources are able to tell us; in other words, these languages must be the continuations of a once existent “proto-language,” or, to quote William Jones, who, after having studied Sanskrit in India for several years while serving as a judge in Fort Williams (now Calcutta), inaugurated a whole new academic field with his famous words:

The Sanscrit language, whatever be its antiquity, is of a wonderful structure; more perfect than the Greek, more copious than the Latin, and more exquisitely refined than either, yet bearing to both of them a stronger affinity, both in the roots of verbs and in the forms of grammar, than could possibly have been produced by accident; so strong indeed, that no philologer could examine them all three, without believing them to have sprung from some common source, which, perhaps, no longer exists.” (William Jones, as quoted in Cannon 1991)

The fact that all these languages are indeed descendants of a lost language—most commonly called a proto-language, in this case Proto-Indo-European—is nowhere disputed today, but there is still no consensus on when and where this original language was spoken, or by whom. Most scholars today agree that the time of the dispersal, and finally disintegration, of this hypothetical group of Proto-Indo-European

speakers must have been in the late Neolithic (i.e., very tentatively between 8000 and 4000 BCE); on the original location opinions still abound, but southern Russia and the Ukraine, Anatolia, or the Ponto-Caspian steppe region are most often mentioned as possible candidates.

Another surprising result of the methodological study of language relationship was the discovery that Malagasy, the dominant language of Madagascar is, though geographically located in Africa, most closely related to languages as far afield as Indonesia, more precisely of the island of Borneo (Kalimantan), which implies a prehistoric maritime expansion of the ancestors of the Malagasy people over a considerable distance.

A further example is the discovery that the languages of the North American Apache tribes (located mainly in the southwestern United States) are most closely related to languages of the Athabaskan group, whose speakers live mainly in sub-Arctic and Arctic Canada and Alaska, showing that these culturally very divergent groups of Native Americans belong together historically.

It should be mentioned, however, that historical linguistics is not always that successful. The peopling of the Americas by migration across the Bering Strait is a well-established fact of prehistory, arrived at mainly by the application of archaeological methods; it should thus be expected, therefore, that at least some Native American languages would turn out to be genetically related to at least some languages of the Old World (such as Siberian languages). Although linguists and laypeople alike often proposed the idea of “Cross-Bering families,” a methodologically acceptable demonstration of such a connection is still lacking (with the possible exception of the Eskimo-Aleut family being relatable to some Siberian groups, among them maybe Uralic).

Language Isolates

Some languages have defied all attempts at classification and remain for the linguistic sciences what are usually called language isolates. Some of the better-known examples are Basque in the Pyrenees,

If you talk to a man in a language he understands, that goes to his head. If you talk to him in his language, that goes to his heart. • Nelson Mandela (b. 1918)

Burushaski in the Karakorum Mountains, ancient Etruscan in Tuscany, Ainu in Japan, and the first language to be put into writing—Sumerian—in what is now southern Iraq. Two major languages of East Asia, Japanese and Korean, are often said to be part of the so-called Altaic language family (which also comprises the Turkic, Mongolian, and Manchu-Tungusic languages), but many scholars now question the validity of Altaic as a genetic grouping, though some experts continue to view Japanese and Korean as being related at least to each other, and thus these important languages may have to join the roster of language isolates.

Accepted Language Families

Well-established and uncontroversial language families include Semitic (comprising Arabic and Hebrew, among others) and the larger Afroasiatic family (comprising Semitic, Ancient Egyptian, and other language groups of northern Africa), Dravidian (Tamil and other languages of southern India), Sino-Tibetan (Chinese, Tibetan, Burmese and other languages of the Himalayas and Southeast Asia), Austronesian (Malay, Tagalog, Malagasy, and languages of Oceania), Austroasiatic (Cambodian, Vietnamese and other languages of South and Southeast Asia). In Africa, the large Niger-Congo family is mostly accepted today (with the vast subgroup of the Bantu languages); important language families of the New World are Eskimo-Aleut, Algonkin, Siouan, Uto-Aztecan, Maya, Carib, and Ge, among others. Some specialists combine all aboriginal languages of Australia into one family, “Australian”; others define one big family on that continent, the Pama-Nyungan family, together with a number of others, which are mainly situated in the north and northwest of the continent. Of all major areas, the ethnically and linguistically stunningly diverse island of New Guinea is home to a disproportionately big number of language families, few of which have lent themselves so far to successful attempts of reducing this number. All continents are furthermore home to a number of further, smaller-scale, language families, which cannot fully be enumerated here.

Detecting Language Families

The methods of detecting a valid language family, or of combining established families into larger groupings, which are sometimes called phyla, are complicated and sometimes the object of ongoing scholarly debates. All agree, however, that some language families are so transparent that no special case has to be made for the common origin of their members. The Romance languages, for example, have the rare distinction that their proto-language—Latin—is actually attested. Other examples are Slavic, Germanic, Indic, Turkic, and Semitic. These easily identifiable families usually split up into single languages (subfamilies, branches, sub-branches) relatively recently.

For other families, the existence of which is not always obvious for the untrained observer, an intricate apparatus of methods has to be applied to demonstrate a relationship. A mere structural, or typological, resemblance of languages is now generally rejected as indicative of a valid language family, since it is well known and demonstrated that the typological makeup of languages may change, sometimes quite drastically, over the course of time. Nor may a linguistic classification be based on anthropological or so-called racial criteria, since established language families are known that transcend such boundaries (the Afroasiatic family, for example). Similarities of a general kind—most often observed in the lexicon of languages—may sometimes be no more than the result of mere chance; in other cases they may be the result of areal convergence of the languages in question.

It is generally agreed that a convincing demonstration of the genetic relationship of two or more languages (or families) requires a high degree of regularity of correspondences. In other words, even a large number of similar words may not suffice to demonstrate a relationship if it cannot be shown that the actual sounds (phonemes) making up the words and the affixes (morphemes) of the languages compared correspond to each other in a regular and predictable way. A further requirement that specialists often demand is that the morphological systems of languages within a family be demonstrably matchable

onto one another, and furthermore, that the degree of regularity found in the lexicon be strictly observed in the domain of morphology as well.

Other scholars have at times advocated less strict principles for the demonstration of genetic relationship, but their proposals remain highly controversial and continue to spawn heated discussions even today. The field of language classification is also one in which an unusually high number of amateur researchers continue to develop and publish often very idiosyncratic ideas, which sometimes receive the attention of the general public. It goes without saying that the language isolates mentioned above attract much attention from well-meaning amateur linguists, whose hypotheses—often brought forward with considerable ardor and not rarely used to support some political or nationalistic agenda—may frequently gain wide exposure in the popular press. Meanwhile, the scientific process of the classification of the languages of humankind is still ongoing, and important, even surprising, results may still be expected from it, even if certain issues are still the focus of sometimes-heated debates. One such controversy surrounds the attempts that have been made—and continue to be made—to reduce the number of identified language families to a considerably smaller number, maybe even to one, showing that all languages share one very remote common ancestor.

The Unique Challenge of Language Classification

The work of language classification owes much of its terminology and some of its more general principles and models to the classification of living species in biology. While there are indeed a lot of analogies between the two disciplines, the nature of their respective objects is profoundly different: one of the more important differences between biological and

linguistic classification is the fact that while in biology the fundamental unity of the realm of living beings—that is, their ultimate relatedness—is not in doubt, and classification in biology is more a matter of establishing *closer* relationships between species, in linguistics no such underlying unity is generally agreed upon. Unlike the biologist, the linguistic taxonomist still faces the task of establishing relationships as such in the first place—the alternative being isolated, nonrelatable status for some languages—with some languages and smaller groupings still unclassified and the strong possibility that this state of affairs may remain without remedy.

Language, Standardization of

Language standardization—the process of creating the (usually written) form of a language favored among its speakers—is profoundly intertwined with world history. For example, the language given status in a region has the potential to marginalize some people and privilege others. Conquering peoples often denigrate the language of the conquered, while that same language can become a rallying point for nationalistic movements.

The standardization of languages is the often consciously initiated and sometimes elaborately planned process of creating a form of a language—usually written—that serves as the accepted and favored means of communication among the members of a speaker group, who normally use more or less aberrant variants of this standard language in their daily lives. Typically, the agents of language standardization operate within the boundaries of and with the support of a political community, usually a state, but cases of conscious language standardization without such support, even against the political will of state authorities, or transcending state boundaries, are also known.

The Nature of Language Variation

One of the fundamental constants of human language is its variation. Languages change constantly in time, and languages used by large numbers of speakers display often considerable degrees of differentiation, which may at times impede the possibility of effective communication between speakers of the same language living in geographically separated locations.

It is probably safe to say that no two individuals use exactly the same language. Sociolinguists (students of language in its social context) speak of different idiolects, that is, languages as used by a single individual. In order to be an efficient tool of communication, it is of course necessary that a large number of individuals use, or be able to use, a language (or a variant, more neutrally called a linguistic code), with a reasonably high degree of uniformity. That uniformity enables speakers to communicate with other speakers effectively, ideally well enough that speakers meeting one another for the first time can communicate without problems. A group of individuals who use such a linguistic variant (acquired as any group member's first or native language) may be called a speech community, and their linguistic variant may be loosely referred to as a language. Languages that are used by large speech communities spread over a considerable territory show, more often than not, some degree of regional variation. Regional variants (which may be characterized by linguistic differences in all linguistic subsystems, including, for example, phonology, morphology, syntax, and lexicon) are commonly referred to as dialects. Most speech communities that are sufficiently large to know some degree of social differentiation or stratification develop linguistic variants divided by social boundaries; these are called sociolects. The average member of a larger speech community will typically be a native speaker of a dialect and, where applicable, may use a sociolect as well. Normally, many individuals will be able to use—or at least to understand—other dialectal or sociolectal variants of the larger speech community, especially individuals with a high degree of geographical or social mobility (or both).

It is not always easy to differentiate between a dialect and a language, and the determination is often made according to nonlinguistic criteria. For example, there is certainly no problem in determining the boundaries of the Icelandic language. It is the only indigenous language of the population of Iceland; its internal dialectal differentiation is minimal, and any indigenous population outside of the island does not use it. On the other hand, some languages of continental Europe are not so straightforwardly definable. A case in point may be the language pair formed by Low German and Dutch: Spread over a large territory in northwestern Europe from Flanders to northeastern Germany, speakers from opposite ends of this area will have little or no ability to communicate with one another in their vernaculars; however, the actual linguistic differences largely disappear as one moves from either end to the border zones of the Netherlands and Germany, where local variants spoken by individuals on both sides of the border are close enough to allow unimpeded communication. Such zones, in which linguistic differences increase gradually with geographic distance, are commonly called dialect continua. The fact that variants spoken in one country are referred to as dialects of Dutch, while those on the other side of the border are known as variants of (Low) German, is not justifiable on linguistic reasons, but rather is a consequence of political considerations and language standardization. Cases of sometimes very large dialect continua being differentiated into languages for historical and political reasons are widespread in Europe and elsewhere; examples in Europe include the West Romance dialect continuum (or DC), comprising French, Provençal, Italian, Catalan, Spanish, and Portuguese; the Scandinavian DC, comprising Norwegian, Swedish, and Danish; and the South Slavic DC, comprising Slovene, Serbo-Croat, Macedonian, and Bulgarian. Outside Europe, national languages such as Hindi and Urdu, Thai and Lao, Turkish and Azerbaijani, and Zulu and Xhosa may be mentioned. The fact that all these variants are generally perceived as and officially referred to as languages is due to the existence of nationally recognized standard languages, which

may be close to, but often differ considerably from, the variants (or dialects) acquired as first languages by many speakers.

The Importance of Writing

Whereas in unwritten languages sometimes a certain amount of dialect leveling may be observed (initiated, for example, by a commonly felt pressure to imitate a prestige variant, such as that of a politically or culturally dominant subgroup, a ruling clan, or maybe a center of trade and commerce), language standardization in the narrower sense of the word can only begin with the introduction of writing. Of course, the formation of discernable individual languages out of large dialect continua often precedes any purposeful standardizing intervention; thus, when people in northeastern France began to write in their vernacular (rather than in Latin) in 842 (with the Oath of Strasbourg, which united the Western and Eastern Franks), it marked the beginning of French as a written language, just as the so-called “Riddle of Verona” (a short text, which is possibly the first attestation of colloquial Italian, dating from the ninth century CE) marked that of written Italian. But the early phases of most written languages are—often for centuries—characterized by the parallel use of several regional (and, sometimes, social) variants; thus, premodern phases of written English (especially in the Middle English period) comprise texts in Northumbrian, Southumbrian, Mercian, Kentish, and other variants. The long way to what is nowadays known as Standard (British) English is marked, among other things, by the rise of London and its aristocracy, the works of Chaucer and the Bible translation of Wycliffe and Hereford in the fourteenth century (which set a linguistic standard much imitated and considered authoritative in following times), the codification of English orthography in Samuel Johnson’s dictionary (1755), and other important events.

At the beginning of a literary tradition, scribes and writers most often try to write down their particular vernacular—frequently on the basis of existing orthographical norms of a different language (so,

for example, the orthographic norms of Latin were adopted by those writing in Romance language vernaculars). The need for a unified standard may arise for a variety of reasons: For example, rulers or governments may wish to possess a unified written medium for their realm, which will allow a centralized control of administrative affairs. In modern times, the wish to propagate the idea of a unified nation may drive the efforts to create a national standard language, which is viewed as emblematic of a (possibly new) nation-state. Literate people and learned bodies may wish to define rules regarding how literature should be produced, very often on the basis of the usage of “classical” authors, who are taken as models for all future literature, both in terms of content and aesthetic form. And, of course, regionalist and nationalist movements operating within the boundaries of a larger state may use language and its standardization to propagate the public acceptance of a regional group as a population possessing the right to separate nationhood. In some cases, standard languages that transcend state boundaries are recognized and actively used: all German-speaking countries recognize the standard codified by the dictionaries of the Duden publishing house based in Mannheim, Germany, and in all Arabic-speaking countries the morphological and syntactical (and, for public broadcasting purposes, also the phonological) model of classical Arabic, as codified in the Qur’an, is regarded as the unquestioned norm for any public use of the language. Only in Christian Malta, where Islam plays no role but the vernacular language is a variety of Arabic, has an autochthonous written standard, based on the Latin alphabet, been developed.

Reflecting this roster of motives, language standardization may be driven by a variety of agents, among them individuals (such as, for example, Antonio de Nebrija, the author of a descriptive grammar of Spanish in 1492), autonomous societies (such as the Gaelic League, or Conradh na Gaeilge, in Ireland, active since 1893), semiofficial normative organizations (such as the Norwegian Language Council, or Norsk Språknemnd, founded in 1951), or official governmental bodies (as was the case for the standardization of the welter of official regional languages in

the former Soviet Union). Especially for the latter two cases, in which a government purposefully interferes with the norms of the official language(s) of a state or nation, the term *language planning* is widely used.

Reforms of Orthography

The most widespread and well-known instances of language planning or language standardization are reforms of orthography. They may be motivated by the urge to simplify existing orthographies, which are felt to be too complicated (as has been the case with the simplification of Chinese characters in the People’s Republic of China since the 1950s, the Danish orthography reform of 1948, and the simplification of Russian orthography in 1917). Another possible motive is the political wish to differentiate a language (sometimes quite artificially) from a closely related one spoken in a neighboring nation. Sometimes a different script is used to serve this purpose: a case in point is that of the “Moldavian” language, a variant of Romanian, linguistically barely different from the national language of Romania, but spoken in the territory of the former Soviet Republic of Moldova and written in Cyrillic script until the disintegration of the Soviet Union in 1991 (after which Moldovans not only reverted to use of the Latin script, but even abandoned the name *Moldovan* in favor of *Romanian*). The case of Tajik is similar: Linguistically a variant of Persian, Tajik was written in the Cyrillic script, rather than in Arabic script (as Persian is), when the area was part of the Soviet Union, and Cyrillic continues to be used in present-day Tajikistan. Finally, the case of Serbian and Croatian may be mentioned. These two are mainly differentiated by the use of the Cyrillic and Latin alphabets, respectively (linguistic differences between these variants of Serbo-Croat do exist, but their boundaries do not follow the cultural boundaries between Catholic Christian Croats and Orthodox Christian Serbs).

Standardization activities are, however, not limited to orthography: All linguistic subsystems may be the focus of planning activities. When it comes to the morphology and syntax of languages, however,

Broadly speaking, the short words are the best, and the old words best of all. • **Winston Churchill** (1874–1965)

the possibilities of introducing highly artificial norms that do not have any basis in any of the actually spoken varieties, are naturally limited. Those norms may be based on older spoken and written varieties of the languages, and they may be artificially conserved in a written norm, at times expanding certain usages beyond the scope actually found in the spoken languages. Thus, the use of certain past-tense forms is artificially preserved in written Standard German, while those forms have practically vanished from most spoken variants.

Reforming the Lexicon

Next to orthography, the lexicon of a standard language is arguably the area most often targeted by standardization activities. Two different tendencies may be singled out as most typical here: first, agents of language planning or standardization may feel that the language uses an unwelcome number of foreign elements (loanwords) from a different language, which should be replaced by “native” words; such attitudes and activities are usually referred to as linguistic purism. The donor language may be a formerly politically dominant language, the influence of which planners may seek to reduce after, say, political independence (as was the case with Russian elements in Latvian and other languages of former Soviet republics); it may be the language of a neighboring culture or state or nation, which is viewed as hostile by certain nationalist activists, or as the target of ethnic hatred (which explains the movements against French elements in pre–World War I Germany); finally, in some language communities a general consensus may prevail, at least among the cultural elite, that the language should be more or less kept free of *any* foreign elements; well-known cases of institutional purism include the normative activities of the Académie Française for French, or those of the University of Reykjavik for the Icelandic language, which was and continues to be extremely successful in coining and propagating new words for modern concepts based on the language material of the older Icelandic literature.

The second tendency when it comes to standardizing the lexicon is the planned expansion of the lexicon of a language. This is often felt necessary when a language is adopted as the standard written medium of a newly independent nation, but language politics for minority languages with official status in the former Soviet Union were also characterized by this tendency, as are language politics for official minority languages in the People’s Republic of China. In some cases, the adopted language may not have been used widely in writing before (or only for limited purposes), and widely known and usable lexical items for numerous purposes (technical, legal, scientific, political) may be lacking; often in such cases, language planners introduce loan elements from another language; if nationalistic ideology does not intervene, the languages of former colonial powers may remain sources of the expansion of such vocabularies (for example, the role of English as a source for modern terminology in most written languages of India, or that of French in many languages of western Africa).

Sometimes language standardization or planning activities may lead to rather unusual results: In this context, the phenomenon of *diglossia* should be mentioned. *Diglossia* is the presence of two different written norms for one language in one society. One example is modern Greek, in which well into the twentieth century two written norms competed for general acceptance, one based upon ancient Greek and considered more “pure,” and the other based on contemporary vernacular Greek (which gained much ground as the twentieth century waned). A second well-known example is that of Norwegian, in which both a city-based written norm that resembles Danish and a more countryside-based, “reformed” (i.e., largely purged of Danish characteristics) norm continue to be used side by side.

Language planners may choose a language as the national standard that is not spoken by any sizable population in their country at all, as was the case with the adoption of Urdu as the national language of Pakistan. Urdu was the (written) variety of Hindustani used in large parts of India, including the city of Old Delhi. Felt as emblematic for the new Islamic nation

of Pakistan, it was adopted as its national language, although only in a relatively small pocket around Karachi was it used as a native language (Sindhi, Punjabi, Baluchi, and Pashto being more widespread as first languages in the country).

Finally, there is one case in which a language that actually died out was raised to the status of a national standard through the combined effort of a community with a strong commitment to its national identity and heritage: Israeli Hebrew. Centuries after it had ceased to be anybody's first language, it was consciously revived by Jewish settlers in the Middle East in the early twentieth century, was declared the national language of Israel in 1948, and now boasts around three million native speakers.

Language Standardization and World History

As the examples mentioned throughout this article indicate, language and language standardization are profoundly intertwined with world history. What languages are accorded status in a region affects the lives of peoples in that region, potentially marginalizing some while securing the fortunes of others. It is not surprising that conquering peoples try to stamp out or denigrate use of the language of the conquered,

nor is it surprising that language becomes a rallying point for nationalistic revolutionary movements. In nation-states in which multiple primary languages are spoken, the degree to which language issues can be amicably resolved is often a strong indicator of the stability of the country. As a political tool, language standardization has the potential both to create unity and to sow the seeds of dissent.

Laozi

(SIXTH CENTURY BCE)

LEGENDARY CHINESE PHILOSOPHER

Laozi, a book also known as *Daodejing* (*The Way and Its Power*) or *The Book of Five-Thousand Characters* (because it contains just about that number of Chinese characters), refers to the text that set forth in eighty-one poems the principles of Daoist philosophy and religion; its alleged author is also known as Laozi.

Laozi (Lao-tzu), who is commonly credited with writing the Daoist classic, the *Daodejing* (*The Way and Its Power*), was among the most influential figures in Chinese history, second to, if not equal to, the philosopher Confucius (551–479 BCE). Ideas in the *Daodejing*, although seemingly mysterious and paradoxical, are subtle and profound and have influenced every aspect of Chinese civilization (government, philosophy, religions, sciences, medicine, arts, and martial arts).

The name “Laozi” means “old master.” Little information about the man exists. The earliest record of Laozi is in *Shiji* (Records of the Grand Historian), written during the Han dynasty (206 BCE–220 CE) by Sima Qian (145–87? BCE). In his biography of Laozi, Qian gave Laozi’s birth name as Li Er, also known as Li Dan, the name of a staff official at the imperial library of the Zhou dynasty (1045–256 BCE). Laozi cultivated learning but did not reveal his knowledge or ability. As the Zhou dynasty declined, Laozi decided to leave. At the city gate, at the request of the gatekeeper, he wrote two books, *Dao* and *De*, with a total of about five thousand characters (words). No one knew where he went then, and Qian wrote that some people said Laozi lived to the age of 160 or 200 and attributed his longevity to the cultivation of *dao* (the Way).

Qian’s account of Laozi’s life includes a visit Confucius made to Laozi. Using Confucius as a medium, Qian referred to Laozi as a dragon, the most auspicious and grand symbol in Chinese civilization to illustrate the breadth, depth, and versatility of his words. Qian also mentioned another person, Lao Laizi, who also wrote Daoist text and who also was the contemporary of Confucius, but Qian did not identify Laozi as Lao Laizi. Some modern scholars question whether Laozi was the contemporary of Confucius and date him in the third century BCE, during the Warring States period (475–221 BCE). Other scholars support Sima Qian’s dating.

During the second century BCE, at the end of the Han dynasty, folk beliefs blended with Daoist ideas and developed the religion of Daoism. After that Laozi was venerated as the founder, and the *Daodejing* became a text with magical and protective power for followers of several schools of religious Daoism. When Buddhism became popular in China, legend claimed that Laozi went to the West and was reincarnated as Buddha. During the Tang dynasty (618–907 CE) Laozi was honored as an imperial ancestor to enhance the prestige of the imperial family, who had the same last name. Temples were built for Laozi, and Daoist monasteries were popular throughout the Tang dynasty. Moreover, the *Daodejing*, as a book about philosophy and governance, was adopted as a text in the imperial government’s civil service examination for sixty-six years, along with Confucian classics. From the third through the tenth centuries “Laozi” was a common name for Chinese intellectuals as well as religious people.

The *Daodejing* consists of eighty-one short chapters of philosophical prose, which often are paradoxical;

I have three treasures. Guard and keep them: / The first is deep love, / The second is frugality, / And the third is not to dare to be ahead of the world. / Because of deep love, one is courageous. / Because of frugality, one is generous. / Because of not daring to be ahead of the world, one becomes the leader of the world. • Laozi (c. sixth century BCE)

therefore, commentaries on the text became important. Ho-shang Gong's commentary of the Han dynasty and Wang Bi's commentary of the fifth century became the standard version. Recent tomb excavation unearthed an earlier version of this text that has slight variations. Some scholars believe that the *Daodejing* is an anthology by more than one author. The thought in the book, however, is consistent.

The *Daodejing* states that a metaphysical, all-encompassing, and organic *dao* (Way) is the originator and sustainer of all things in the universe. It can't be described. As the *Daodejing* states, "the *Dao* that can be told is not the constant *Dao*," yet this *dao* is modeled after naturalness or spontaneity and can also be discerned in ordinary or even lowly things.

The *Daodejing* draws its inspiration from the observation of nature, for which it has a profound preference. It exhorts frugality, contentment, and tranquility and promotes few desires. Moreover, contrary to common assumptions, it claims that the weak overcome the strong and that the soft overcome the hard. The *Daodejing* states, "Of all things in the world, nothing is more soft and weak than water, yet none could rival water in dissolving the hard and the strong." Some scholars believe that the *Daodejing* teaches people means of self-preservation during troubled times. The *Daodejing* also proposes ways for a sage ruler to govern. Its ideal society is a simple and primal society where people are content. Moreover, its best government has only a shadowy existence: it interferes little with people's lives either in taxation or labor conscription. The *Daodejing* states, "I [the ruler] practice *wu-wei* [nonactions] and the people were self-transformed; I love tranquility, and the people became pure and good . . ." But the *Daodejing* is not just a creed for simplicity and contentment, it also embraces and understands changes, making it a seemingly simple but profound text.

Ideas in the *Daodejing* have been applied in Chinese government, notably during the early Han dynasty under the emperors Wen and Jing (180–141 BCE). Under the name of "Huang-Lao" (combining the name of the legendary Yellow Emperor with "Laozi"), the early Han government was frugal and nonactive and levied light taxes to allow citizens to recover from the heavy taxation and wars of the previous Qin dynasty (221–206 BCE). Near the end of the Han dynasty and for the next several centuries, religious Daoism thrived. People revered Laozi as a deity; philosophers adopted ideas from the *Daodejing* and eventually wrote a large collection of Daoist scriptures. Daoism also influenced Chinese arts. Along with *Zhuang Zi* (Master Zhuang), another Daoist classic written during the Warring States period, the *Daodejing* inspired literati landscape painting, most notably during the Song dynasty (960–1279). The scene was usually of one or two scholars strolling among mountains and trees. Daoist ideas also inspired many of China's most treasured poems. People often consider Li Bai (701–762 CE), a Daoist of the Tang dynasty, to be China's greatest poet.

During the early Qin dynasty Daoism also inspired Chinese primitive sciences and martial arts and influenced Chinese medical theories and practices. Daoists' search for a longevity elixir promoted the development of alchemy (a chemical science and speculative philosophy that aimed at, among other goals, the discovery of a means of indefinitely prolonging life).

Laozi's *Daodejing* fundamentally changed Chinese civilization. It balanced goal-oriented, ethically motivated, and duty-bound Confucianism with a sense of individual freedom in its tranquil appreciation of the beauty of nature and understanding of changing and unpredictable fortunes. Since the late eighteenth century the *Daodejing* has also attracted many Western minds. Today it is one of the books most

translated into English. Scholars and laypersons explore and perceive its ideas from different angles, comparing it with Christianity, appreciating its tranquility and love of nature, seeking an individual's freedom from highly structured modern society, or simply studying the ritual and practices of the religion of Daoism. Western intellectuals have freely interpreted and explored the text in their own search for a space in a highly standardized and bureaucratic world. Regardless of whether Laozi or more than one author wrote the *Daodejing*, it has significantly influenced Chinese civilization, and its influence has spread beyond the Chinese horizon and into world history.

Latter-Day Saints

The Church of Jesus Christ of Latter-Day Saints (LDS), also called the Church of Jesus Christ, is the fifth-largest Christian denomination in the United States. The church is often called the “Mormon” church because of members’ adherence to *The Book of Mormon: Another Testament of Jesus Christ* as scripture in addition to the Bible.

Headquartered in Salt Lake City, Utah, but with members in more than 160 countries in 2010, the Church of Jesus Christ of Latter-day Saints has quickly established itself as a significant world denomination. Scholars have referred to it as “a new religious tradition” (Shipp 1985, 149) and have seen in its growth “the rise of a new world faith” (Stark 1984, 18).

Founding and Membership

The Church of Jesus Christ was founded on 6 April 1830, in Fayette, New York, by Joseph Smith Jr. (1805–1844), who, as a fourteen-year-old boy, sought an answer to which of the many competing Christian denominations he should join. He testified that he was visited by God and Jesus Christ and was instructed to join none of the denominations. Church members believe that Joseph Smith Jr. was called as a prophet and received divine revelations, many of which were published in the *Doctrine and Covenants*, a book that details Smith’s received revelations. It is now part of the Latter-day Saint canon of scriptures.

Since the time of Joseph Smith Jr., the Church of Jesus Christ has experienced dramatic growth. By the

end of 2009 the church had a worldwide membership of about 13.8 million. Less than half of Latter-day Saints live in the United States and Canada. Some countries in the South Pacific and many Latin American countries and regions have comparatively large Latter-day Saint populations, including Mexico, the Caribbean, Central America, and South America. The church is still a small minority but has experienced substantial growth in Asia, Africa, and Europe.

Basic Beliefs and Practices

Core teachings of the church include beliefs in Joseph Smith Jr.’s call as a modern-day prophet, the church as a restoration of the original pure Christianity established by Jesus Christ during his mortal ministry, acceptance of *The Book of Mormon: Another Testament of Jesus Christ* as a translation of records of ancient prophets in the Americas and, with the Bible, as divine scripture. Church members believe in Christ and see him as the head of their church, but the church does not belong to the Catholic, Protestant, nor Eastern Orthodox families of churches. Many of the basic beliefs of the church are stated in the *Articles of Faith*. Key doctrines include the restoration of divine priesthood authority; continuing revelation to church members and modern prophets; high moral standards of honesty, chastity before marriage, and fidelity after marriage; and a health code that prohibits the consumption of alcohol, tea, and coffee and any form of substance abuse. Church members pay one-tenth of their incomes to the church as a tithe and are encouraged to fast monthly and give the money they would have

Stipple drawing of the prophet Joseph Smith.

spent on food, or more, to a fund to help the needy. The church also has an extensive welfare program, designed to meet the temporal needs of church members who are unable to provide for themselves or their families.

The Church of Jesus Christ had 130 operating temples throughout the world as of 2009, which are used to conduct ordinances such as marriage ceremonies, but are not used for ordinary weekly worship services. Latter-day Saint doctrine teaches that marriages solemnized (“sealed”) in Latter-day Saint temples do not dissolve at death and that the family is the core unit of the church and society. The church also encourages education and offers a subsidized loan fund for members seeking higher education in developing countries. The church also has an extensive educational system, including Brigham Young University in Utah, one of the largest private universities in the United States.

Many university-age single men and women, as well as retired married couples, serve as full-time missionaries for the church around the world for one to two years. At the end of 2009 more than fifty thousand missionaries were serving at their own expense in the region of the world they were assigned to by church headquarters; in many cases they learn a foreign language to serve. Local leaders of the church are not salaried ministers. They, along with most members who serve as part-time teachers, leaders, and youth leaders in local congregations, are lay volunteers who give of their time for a few years in an assigned church position while continuing normal employment.

Historical Development

The early years of the Church of Jesus Christ were marked by persecution and movement westward. During the first two decades of the church, members were driven to Ohio; to Independence, Missouri; to Far West, Missouri; and, after being the subject of an extermination order by the governor of Missouri, to Nauvoo, Illinois. After the martyrdom of Joseph Smith Jr. at the hands of an angry mob in 1844, the Latter-day Saints eventually migrated 2,000 kilometers west to Salt Lake Valley, now part of Utah, under the leadership of the second president of the church, Brigham Young (1801–1877). After moving to Utah the Latter-day Saints faced an occupying army from 1857 to 1860, sent by U.S. President James Buchanan, who acted on false rumors of a Latter-day Saint rebellion.

Early official persecution and mob violence against Latter-day Saints constitute one of the harshest examples of religious persecution in U.S. history. Friction arose from religious, cultural, and political differences with their fellow frontier people, particularly over issues of slavery, which was legal in Missouri, and fears of Latter-day Saint political domination.

Another point of contention was the Latter-day Saint practice of polygamy (plural marriage), which was publicly taught from 1843 until it was discontinued in 1890, and efforts by the Latter-day Saints to establish economically self-sufficient

Mormon Temple, Salt Lake City. Courtesy of L. Tom Perry Special Collections, Harold B. Lee Library, Brigham Young University.

communities. Fears of Latter-day Saint practices led to federal U.S. legislation from 1849 to 1896 attacking polygamy, denying civil rights to polygamists and nonpolygamous members of the church, and dissolving the Corporation of the Church of Jesus Christ of Latter-day Saints. Legal challenges by Latter-day Saints to antipolygamy legislation resulted in the first U.S. Supreme Court cases interpreting the free exercise clause of the U.S. Constitution: *Reynolds v. United States* (1878) and *Davis v. Beason* (1890), which upheld federal legislation against both polygamy and the Church of Jesus Christ.

Despite the persecutions of the early years of the church, missionary work continued to fuel its growth. During the 1840s thousands of people joined the Church of Jesus Christ from missionary efforts, particularly in Great Britain, and immigrated to the Americas. As early as the 1850s, missions were opened in Chile, France, Germany, Gibraltar, Hawaii, India, Italy, Malta, Scandinavia, South Africa, the South Pacific, and Switzerland. Since that time international missionary efforts have increased, but by the 1920s church policy no longer encouraged members to gather at a central geographical region.

During recent years the international growth of the church has been increasingly reflected in LDS demographics. By 1996 more church members lived outside the United States than inside, only 30 percent of members lived in the western United States,

and fewer than 20 percent lived in Utah. As of 2009 church members belonged to 28,424 local units; church materials are available 166 languages. Since the late 1960s the church has had a growth rate of about 50 percent per decade. Based on this growth rate, the sociologist Rodney Stark has argued that Latter-day Saints “will soon achieve a worldwide following comparable to that of Islam, Buddhism, Christianity, Hinduism, and the other dominant world faiths” (Stark 1984, 18).

Law, Civil

One major accomplishment of the Roman Empire was the development of a civil law system comprising statutes, forms of procedure, judicial decisions, imperial edicts, senate legislation, opinions of jurists, and the assimilation of some local customs across its vast territory. By modern times civil law applied to most of the world, with the exception of Britain and its domains.

What began as Roman law, *ius civile* (“citizens’ law”), became an imperial, continental, and then a global organizing principle. Roman law started as a set of binding rules that aimed to ensure harmony and facilitate commerce by confronting challenges, accommodating change, creating institutions, embracing legal concepts, and enshrining oral customs in a written format. Civil law did not usually apply to slaves. The goal was to fully regulate the lives and relations of citizens.

Civil law had diverse, incremental sources. Composed of statutes, basic forms of procedure, decisions by judges, imperial edicts, senate legislation, opinions of jurists, and the assimilation of some local customs, civil law helped consolidate the management of a heterogeneous empire. The development of uniform laws across its vast territory throughout Europe, the Middle East, and North Africa was one of the most notable accomplishments of the Roman Empire. By modern times civil law applied to most of the world, with the exception of Britain and its domains.

Ancient Rome

In 450 BCE, Roman leaders (consuls) proclaimed the Twelve Tables that organized public prosecution and

punishment of crimes while instituting an adjudication of civil disputes. Common people (plebeians) were to be protected from the predominance of the privileged class (patricians). Male heads of families (patriarchs) wielded decisive power over their families.

Beginning in 366 BCE, praetors (magistrates from the social elite who administered justice) clarified philosophical and practical conflicts. They also proclaimed the principles of justice by which they would interpret the letter of the law. The spirit of the law was typically conservative, aspiring to protect lives, property, and the reputations of citizens. Correcting wrongs and reversing injustice were additional guidelines. Growing relations with foreigners who lived under Roman jurisdiction (or close to it), necessitated the formation of the *ius gentium* (“peoples’ law”). Its application did not discriminate between people on the basis of their citizenship. This concrete framework, coupled with *ius naturale* (“natural law”), a more philosophical set of principles, facilitated a more universal conception of laws.

Gaius (flourished 130–180 CE) authored the Institutes (“foundations”) around 130 CE. This treatise analyzed Roman law and serves as a major source for civil law. The Institutes described the different status persons possess; belongings, and how ownership is acquired, including wills; interstate succession (what to do when a person dies without leaving a will) and obligations; and various forms of actions (how to properly conduct legal issues).

Justinian’s Contribution

The roots of civil law as conveyed to subsequent generations are derived primarily from Roman law as

Good laws are the offspring of bad actions. • Charles Macklin (c. 1697–1797)

preserved and formulated by legal experts commissioned by the Byzantine emperor Justinian I (527–565 CE). He wanted to provide a systematic imperial law amid confusion after centuries of contested decisions. A further reason was to highlight, in Latin, the legitimacy and piety of Roman traditions as a proper foundation for Christian communities, and in the process position himself as an enlightened, reform-minded leader, thus consolidating his own political authority.

The result was the *Codex Justinianus* (Justinian Code), proclaimed in 529 CE. Justinian then commissioned sixteen lawyers to order and codify the legal opinions of the Roman *jurisconsulti* (“legal experts”). They issued the *Digest* of Roman jurisprudence (much of which transmitted, verbatim, Gaius’s Institutes) in 533 CE. In the same year, Justinian’s team published a handbook of civil law, which was to serve as a textbook for law students. Through its name, Institutes, they clearly tried to build upon, and replicate, the reputation of Gaius’s work four hundred years earlier.

An authoritative version of the *Codex Justinianus*, updated through the labor mentioned above, was published in 534 CE. Justinian forbade any commentary on the Digest, and possibly on the other legal instruments as well, making this *corpus juris civilis* (“body of civil law”) the normative standard for over a millennium. Finally, although the project was completed only after his death, Justinian inspired the composition of the Novels, new laws issued—primarily in Greek, symbolizing the political transfer of power to Byzantium—after the Corpus.

Overall, these compilations reflect quite accurately contemporary Roman laws. In the legal heritage that was his legacy, Justinian exuded confidence in his own understanding of God’s guidance to the type of Christianity he espoused, but showed little tolerance toward any other versions, much less to Jews or pagans. Perhaps thanks to the influence of his controversial wife, Theodora (c. 497–548 CE), Justinian improved the status of women. He was also particularly attentive to equitable administration of the provinces.

The Middle Ages

Justinian’s volumes were coupled with incremental jurisprudence composed of judicial decisions, the opinions of legal scholars, wide public obedience toward emerging norms in criminal, commercial, and maritime law, and evidence of continuous custom. These were complemented by canon law. Combined, they serve as the sources of modern civil law.

After the breakdown of the world order that followed the gradual collapse of the Roman Empire around 500 CE, civil law was used by the multiple successor sovereignties and political entities. It thus became the organizing legal principle of continental Europe. Charlemagne (Charles the Great, reigned 768–814 CE) relied on Roman traditions to derive legitimacy and for practical reasons. When, blessed by Pope Leo III (reigned 795–816 CE), Charlemagne established the Holy Roman Empire on Christmas Day 800 CE, the principles of its civil law governed matters of private law, together with local Frankish customs and notions of Christian justice.

The Modern Era

Starting from the sixteenth century, the civil law system expanded to the colonial territories of European states—including France, Belgium, Portugal, and Spain—in Latin America, Asia, and Africa. Other countries affected by contact with European powers, such as Japan and China, also adopted civil law. Socialist countries, beginning with Russia, adopted it as the legal system. Civil law has also served as the foundation for the principles of international law. The Roman phrase *ius gentium* (commonly translated in this context as “the law of nations”) was the initial designation for the legal system that addressed more than one center of sovereignty.

The most important example of a modern *corpus juris civilis* is the 1804 Napoleonic Code. It became a role model for others, thanks to its relatively inclusive and progressive spirit, especially the emancipation of religious minorities such as the Jews. Napoleon Bonaparte (1769–1821) consolidated

With customes wee live well, but Lawes undoe us. • **George Herbert (1593–1633)**

French influence, and his own rule as an emperor, over a considerable segment of the world amid his wars with Britain and its allies. His code has three parts (governing personal status, property, and the acquisition of property), roughly corresponding to the structure of the *Codex Justinianus*.

Relationship with Common Law

Civil law is distinguishable from the British common law tradition, established after William the Conqueror successfully invaded England in 1066. Historically, there were substantive differences. Whereas common law relied on unwritten custom, then on long renderings of judicial opinions primarily affirming or rejecting precedents, civil law is based on detailed, explicit clauses in binding codes or other legislative acts, and on short judgments interpreting and applying the norms exemplified by such binding instruments. In addition, as its name denotes, common law only applied, at least initially, to the lower classes in the empire, in England and beyond, but not to the monarchy and the titled aristocracy. The jurisdiction of civil law, in contrast, was meant to be more comprehensive, incorporating all citizens. In reality, however, many of these distinctions were more semantic than substantive.

Some places, such as the Canadian provinces of Quebec and New Brunswick, and Louisiana in the United States, because of their considerable French heritage, possess strong civil law traditions (in 1774 the British Parliament passed the Quebec Act allowing this territory to retain the French civil code; Louisiana adopted its own code in 1821). Because they are part of a federal framework, the ultimate authority over such jurisdictions is vested in their supreme courts, where the majority inevitably comes from areas governed by common law; Canadian custom allots Quebec three of nine seats in the Supreme Court.

The Future

Since World War II, and the speedy availability of case law and scholarly research to most interested

jurists and institutions, common law and civil law converge much more than they diverge, linguistic and cultural distinctions notwithstanding. As the harmonization of laws necessitated by globalization continues, civil law may come to be remembered more as a relic of the past than a unique organizing principle, even in continental Europe, where its legacy cannot be erased. The pioneering importance of civil law will serve as guidance as international law expands into dimensions hardly known or practiced until the twentieth century, such as the promotion and protection of human rights and the environment.

Law, Contract

Contract law is the body of law that regulates and enforces promises and exchanges, for either immediate or future performance, between two or more consenting parties. It also provides legal remedies if one or more of the parties break these agreements.

Contract law fulfills a moral, social, and economic function. The moral function of contract law is rooted in the premise that promises made are to be kept, which is almost universally recognized in customary law, as well as to varying extents in positive law. Socially, contract law is a means for regulating and defining social relationships, such as in the case of marriage contracts, or contracts between different social orders or castes. Economically, contract law facilitates commerce by providing a form of legal guarantee of remedies for broken contracts, which facilitated the development of long-term trade, as well as the use of negotiable instruments, such as letters of credit and bills of lading.

Moral Functions of Contracts

The legal scholar Harold J. Berman wrote that the Western ideal of contract law began with the theory that “a promise created an obligation to God” (Berman 1986, 112). Not only does the canon law of the Jewish, Islamic, and Christian faiths affirm this idea, nearly all cultures have a form of contract premised on the moral notion that promises are to be kept. In traditional India and China, contracts were often adjudicated in terms of moral principles (dharma in Hinduism; *li* in Confucianism); a contract which violated general rules of morality or equity could be ruled invalid, even if

the acts were otherwise licit. Roman law mandated that contracts be “clothed,” that is, parties must have had a tangible purpose or reason (*causa*) for entering into a contract. Therefore, Roman law emphasized the binding nature of the promises made between parties, and in determining the legality of a contract, jurists in the Roman law tradition privileged the ends, or the reasons for creating the contract over the means by which the contract was created. Medieval canonists added an element of Christian morality to contract law which held that the final purpose of a contract, regardless of the intermediate expectations of the parties, must conform to moral principles. The Civil Code of Napoleon (1804) mandated that a valid contract was one to which parties voluntarily agreed, and that was done for licit purposes; the form of the contract was secondary to the ends. In Anglo-American common law, principles of equity applied as well, and the doctrine of unjust enrichment meant that courts could order quasi-contract actions, which are court ordered adjustments to contracts that are meant to restore equity between the parties, to recover sums from those unjustly enriched on behalf of plaintiffs.

Social Functions of Contracts

For most of the history of traditional China and Japan, there was no formal contract law, although other laws, such as imperial or feudal laws, could be used to seek legal protection and remedies in contract disputes. Moreover, customary law in China and Japan served the purposes of substantive contract law. This customary law was closely bound to the social structures of each society: the Confucian familial and clan hierarchy in China and the feudal system of traditional

Japan. In China, the Confucian ideal of the family, which dictated strict obligations between individual family members, relationships of whole family units to each other, and to the society as a whole, superseded any individual contractual relationships. In other words, contractual relationships were bound first by the Confucian system, and only secondarily by the individual agreement. Traditionally in China, recourse to the courts was considered the very last resort in a contract dispute; arbitration was almost always preferable, because an irresolvable dispute signified a small breakdown in the traditional Confucian order. Similarly in Japan, contract disputes were almost always subject to mediation, except that where in China the family or clan formed the basis of arbitration, in Japan the feudal village more than the family was the operative unit. In the West, contract law formed part of a broader law of obligations which similarly defined social relations. The intricacies of the Roman system of patronage meant that Roman law considered “like” contracts (*obligationes ex quasi contractu*), such as the giving of gifts, to be a source of legally binding relationships. Even in modern business practice, as Stewart Macaulay has observed, contracts are less a means of regulating exchange than a method of building relationships, and a breach of contract is a serious break which “often results in a ‘divorce’ ending the ‘marriage’ between the two businesses, since a contract action is likely to carry charges with at least an overtone of bad faith” (Macaulay 1963, 65).

Economic Functions of Contracts

The English legal scholar Henry Maine wrote that a shift from “status to contract” was fundamental to the creation of modern social and economic systems (Maine 1917, 100). In other words, modern (i.e., Western) legal systems, contractual relationships, and economic systems depended on the social equality of the parties, the ability to freely enter into exchanges, and the confidence the law would enforce these exchanges. In ancient Greece, by comparison, although Athenian contract law allowed for absolute freedom to enter into contracts, in practice this only applied to citizens of

the polis. In the seventeenth century, English jurists began to emphasize the concepts of “consideration” and the “bargain,” which, although similar to the Roman concept of *causa*, differed in that English common law generally did not consider either the ends of a contract nor the status of the parties involved. Instead, English law concentrated on the bargaining between parties from which a consideration, an act or promise by which one party acts in consideration of a reciprocal action, creates a binding agreement. English common law also developed the doctrine of “strict-liability,” which placed an absolute binding obligation on the parties regardless of the reason for nonperformance. In *Paradine v. Jane* (1647), a lessee was still bound to pay rent to his landlord, although the defendant’s lands and crops had been destroyed during the English Civil War, because the court ruled that contracts are entered into freely by the parties involved. This seemingly harsh measure, however, has been undeniably important in the development of commerce and trade by making negotiable instruments, such as letters of credit, checks, and bills of exchange (all of which are essentially contracts which promise future payments), a more efficacious way of transferring large sums of money, because no matter how many parties that negotiable instrument has passed, the recipient could expect payment because “strict liability” still bound the original issuer to the original contract.

Historians and Contract Law

The intricacies and formalities of contracts and contract law have often been imposing to the point that many historians have disregarded contract law as a subject of inquiry. However, contract law, even in its most formal expressions, reflects the historical context in which the law was created, or contract disputes adjudicated. Moreover, as the American legal scholar Lon L. Fuller observed, contract law is not only the positive law of contracts, but an expression of customary law, and thus “contract law...refers primarily, not to the law *of* or *about* contracts, but to the ‘law’ a contract itself brings into existence” (Fuller 1969, 14). Thus, for the historian, contract law can yield

important information about culture, ideology, society, and economics and a valuable point of inquiry into the past.

Law, International

International law has been evolving for centuries to provide a framework for international and transnational activities. Like other areas of the law, its purpose is to allow participants to deal with each other with some level of predictability and thus to reduce misunderstandings and to avoid conflicts and confrontations.

International law, with its primary goal of providing a structure for dealings among international and transnational governments, is a more primitive system of law than the domestic legal systems found in advanced nations. It does not have a legislative body with the capacity to enact laws binding on all nations, an executive branch or a military or police force that can enforce the laws that do exist, or judicial tribunals that have broad jurisdiction or the power to issue binding and enforceable decrees in many circumstances. Although early versions of such bodies can be found in the United Nations and in emerging regional organizations, the process of constructing institutions that enjoy widespread support and can meet the challenges presented by a deeply divided world is just beginning.

Some have argued that international law is not really law because a superior body cannot enforce it. But most commentators contend that because most countries follow international law most of the time, and because those countries that violate its norms do frequently suffer consequences, it should be viewed as a system of law.

International law is less developed than other systems of law because the larger and more powerful nations do not always accept that it is in their interest to subordinate their self-interest to an international or

multinational rule. Although smaller nations will see the benefit of an international structure that protects the weak against the powerful, the stronger nations do not always agree that such a structure is beneficial. The foundations of international law have always been reciprocity and enlightened self-interest.

Sources of International Law

The primary sources of international law are treaties—bilateral and multilateral—and “customary international law,” which emerges from the actual practices of states and is undertaken with an understanding that these practices are required by law (*opinio juris sive necessitatis*). The “practices” of states are usually found in actions taken by a country, but they can sometimes be discovered in the statements their diplomats or leaders issue or in their votes at international organizations or diplomatic conferences. To become “custom,” a practice must have the widespread (but not necessarily universal) support of countries concerned with the issue and must usually have continued for a period of time long enough to signify understanding and acquiescence. Occasionally a regional custom can emerge, if the countries of a certain part of the world order their affairs in a certain manner.

In recent years, it has become accepted that some principles of customary international law are so important that they are called “peremptory norms” or “*jus cogens*” (commanding law) and that no country is permitted to depart from these principles. Among these norms are the prohibitions on aggression, genocide, crimes against humanity, slavery, extrajudicial murder, prolonged arbitrary detention, torture, and racial discrimination.

Although most historical summaries of the development of international law focus on its growth in Europe and the West, the reality is more complex. Practices governing interactions among nations and peoples also developed in Asia and elsewhere, and these norms have been merging with those that came to be accepted in the West. The growing recognition that groups, as well as individuals, have human rights protected under international law is an example of a non-Western contribution to international law.

Emergence of Modern International Law

Most scholars explain that “modern” international law emerged in Europe at the time of the Renaissance and Enlightenment through the Peace of Westphalia, which ended the Thirty Years War (1618–1648) and gave formal recognition to the sovereign state system. This treaty-based system was designed, in part, to allow Catholic and Protestant states to coexist in Europe. International law became necessary to confirm the boundaries among these states and to bring some order to their dealings with each other. Countries accepted the doctrine of *pacta sunt servanda* (treaties are to be observed), now a fundamental principle of international law, and established some machinery for the settlement of disputes. During the years that followed, citizen participation in government grew in England and then in France through the French Revolution. As monarchies crumbled, individuals, corporations, nongovernmental organizations, and international organizations emerged as part of the international legal system.

The Final Act of the Congress of Vienna (1815), signed by Austria, France, Great Britain, Portugal, Prussia, Russia, and Sweden, which formally ended the Napoleonic Wars, was another significant event, because it created a system of political and economic cooperation in Europe and also articulated governing norms of international law. Among the principles that emerged from this Congress was a set of rules governing diplomatic protocol, a condemnation of the slave trade, the principle of free navigation (not only for the

riparian states but for all states) on the major rivers of Europe, and the neutrality of Switzerland. Treaties, both bilateral and multilateral, began to cover a wide range of topics, supplementing and sometimes replacing custom as a source of law.

During the period of colonial expansion that took place in the last half of the nineteenth century, the concepts of international law that had been utilized in Europe and the West were introduced into Asia by the Western powers. Western international law was then even more primitive than it is today. No global institutions existed, and only a few special-purpose regional organizations had been created. Some topics—such as diplomatic immunity—were fairly well defined, and consensus had also been reached on the important goals of stopping piracy and slavery.

Laws of Armed Conflict

War was still viewed by many as an acceptable instrument of foreign policy, but the dramatic increase in destructive weaponry resulting from the industrial revolution caused many to realize that some constraints were needed on the use of force. Major international meetings were called, the most significant being the 1899 and 1907 Hague Conferences, which were designed to codify the laws of armed conflict and establish limits on certain types of military activities. The growth of daily newspapers in the industrialized countries had the effect of allowing common citizens to participate more fully in policy decisions, and led, in many countries, to a democratization of international politics.

Twenty-five nations attended the 1899 Hague Conference, which was convened by Czar Nicholas II of Russia, and a larger number ratified the documents produced by the meeting, which included conventions governing the conduct of warfare and the peaceful settlement of disputes. Although European nations dominated these negotiations, nineteen Latin American nations signed or ratified one or more of the documents, as did China, Japan, Korea, Persia, Siam, and Turkey.

An unjust law is itself a species of violence. Arrest for its breach is more so. • Mohandas Gandhi (1869–1948)

The 1907 Hague Conference, called again by the Russian Czar Nicholas II upon the urging of Theodore Roosevelt, produced additional conventions designed to limit the scourge of warfare. The European nations again dominated the negotiations, but eighteen Latin American nations signed or ratified one or more of the conventions (Honduras was missing), as did China, Japan, Persia, Siam, and Turkey (with Korea missing because it had become a protectorate of Japan). Liberia also adhered to many of the conventions.

Natural Law vs. Positive Law

The nature of the evolving international legal system was described by many as one of consent—or “positivism”—wherein only those norms agreed upon by states could be enforced against them. But perhaps because of the theocracies that had governed many parts of Europe in previous centuries, the Canon law that had developed during that period, and the religious fervor that still burned brightly for many others, contended that certain inherent principles also governed nations. Tension emerged between this “natural law” formula as the basis of international law and the perspective of “positivism” promoted by others, and this tension still exists today.

The Dutch diplomat Hugo de Groot, who wrote four hundred years ago under the Latin name Grotius, is often called the father or founder of international law because he tried to reconcile natural and positive law. His analysis of the laws of war, the law of the sea, and the protection owed to diplomats laid the framework for modern thinking on these topics. He believed that a “law of nature” could be deduced by logical reasoning, rather than by resort to divine sources, and thus tried to formulate a law that could be acceptable to all, conceivably even to “infidels.”

Another continuing issue has been whether international law is incorporated into national legal systems, and is thus part of the law applied by national courts (“monism”), or whether it is a separate and distinct legal system governing nations but not accessible by normal citizens in disputes in domestic courts (“dualism”).

Continuing Challenges of a Divided World

After World War I, the League of Nations was established and served to promote dialogue and negotiations, but its efforts to stop the continuing imperialistic activities of some nations were unsuccessful and the world again engaged in massive slaughters in World War II. The 1928 Kellogg-Briand Pact, which outlawed the recourse to war, did not stop warfare, but it at least has required countries to come up with some justification for armed conflict, with “self-defense” being the most common excuse.

The United Nations was established in 1945, and the nations of the world have entered into numerous additional bilateral and multilateral treaties since then on subjects ranging from economic affairs to the law of the sea to human rights to arms control. The U.N. Security Council, with 15 members, including 5 permanent members (China, France, Russia, the United Kingdom, and the United States) that can veto any resolution, has the responsibility to deal with threats to the peace and breaches of the peace. The General Assembly, now with 190 members, serves as a forum for discussion and annually enacts a wide range of resolutions addressing global problems. The International Court of Justice sits in The Hague, the Netherlands, and decides cases brought to it by governments. Numerous more specialized tribunals have also been created.

Regional organizations have been created in almost all areas of the world, with the European Union and other European organizations being particularly effective in addressing regional issues and reducing tensions among nations. Many in the developing and non-Eurocentric parts of the world still view international law as dominated by the West and by the rich and powerful countries, and efforts are continuing to find ways to restructure the United Nations to reflect the world’s diversity more fairly and to allow it to operate more efficiently.

The international legal system is still a work in progress. As the world becomes increasingly

interdependent, international law will become more important and more complex. Countries remain reluctant to give up essential elements of sovereignty and autonomy. But as transnational problems present themselves, transnational solutions will continue to be devised. Through this incremental process, international law will continue to grow.

Law, Natural

Natural Law—which in its most basic sense involves universal, objective, and moral concepts that shape proper personal and political associations—originated in ancient Greece and Rome and continued to evolve through the history of Western civilization as an alternative to other theories about human behavior.

Generally speaking, the Natural Law comprises universal, objective, and necessary moral truths, which define proper personal conduct or the fundamentals of political association. By necessity, this statement is an oversimplification because the meaning and import of the Natural Law has evolved throughout the history of Western civilization—from its genesis in ancient Greece and Rome to its modern, postmodern, and relativist twentieth-century forms. The Natural Law pervades the Western philosophical tradition as an alternative to subjectivist, cynical, or skeptical theories about human behavior and political association.

Natural Law in Ancient Greece and Rome

Although numerous cultures had recognized the basic dichotomy between law as an artifact and law existing outside and independent of human society, ancient Greek culture was the first to raise this distinction as a purely philosophical question. The issue of how to achieve happiness and well-being (*eudaimonia*—from *daimon*, the divinity that presides over the happiness or misery of a human being, and *eu*, meaning “well”) fascinated the ancient Greeks. The philosophy of Natural Law concluded

that *eudaimonia*, which the Stoics would later call the “good life,” involved “living in agreement with nature.” Before Natural Law was explicitly defined in philosophical terms, it was largely implicit in Greek culture, as revealed in Sophocles’ fifth-century-BCE tragic drama *Oedipus the King* (by reflecting on the nature, sources, and consequences of Oedipus’s fate) and in the pre-Socratic metaphysical debates concerning the static or mutable nature of the universe. It was also implicit in Aristotle’s (384–324 BCE) distinction between natural and legal justice. Throughout, the Greeks repeatedly contrasted universal truths grounded in an objective and unchanging reality with subjective beliefs based in mutable facts or on contingent social customs.

In the Hellenistic Era (323–31 BCE), Zeno of Citium (334–262 BCE) explicitly conceived of Natural Law as a central concept of his Stoic school of philosophy. The Stoics maintained that the universe was structured and organized according to rational laws, which were knowable via the one human faculty that shares in this universal reason—the rational mind. These universal, absolute, unchanging laws constituted the Natural Law, and living in agreement with nature (as structured by the Natural Law) was the good life.

Although the Stoics gave birth to the formal concept (and phrase) “Natural Law,” they are not responsible for the long-standing impact that it would have on moral and political philosophy over the next two millennia. The reason is that the original Stoics were determinists. Thus, they believed that living in agreement with nature was solely an issue of aligning one’s internal mental states with the events of the external world that were necessarily determined by Natural

Law. The Stoic ideal was the happy tranquility (*apatheia*) of the person who simply accepts the world for what it is and has to be. There was no role for social or political philosophy in this worldview.

The Romans were heavily influenced by Stoicism, and some of the most prominent Stoic philosophers in the Western canon are Romans, such as Seneca (3 BCE–65 CE), Epictetus (55– c.135 CE), and Marcus Aurelius (161–180 CE). The most prominent Roman Stoic is the lawyer and philosopher Marcus Tullius Cicero (106–43 BCE).

As a lawyer, Cicero rejected Stoic determinism but found the Stoic concept of Natural Law vitally important for practical morality and politics. As the Natural Law comprised what Cicero called “right reason,” it was applicable to (and was accessible by) all people in all places at all times. Thus, it became key to grounding political theory in a moral theory based on a universal human attribute: the human mind or, more precisely, the human capacity for reason.

This conception of Natural Law soon found a role in the unique and revolutionary tripartite division of socio-political rules developed by the Romans. In political and legal practice, the Romans had already conceptualized two types of law: the law of nations (*jus gentium*), an embryonic version of international law, and the civil law (*jus civile*), the particular laws of each sovereign empire or kingdom. Cicero’s conception of Natural Law (*jus naturale*) was incorporated into this structure, serving as a universal, absolute moral foundation for both the law of nations and the civil law. For the first time in Western thought, a universal and absolute moral law was applied to all political institutions and laws.

Modern Theory of Natural Law

Early Church Fathers, such as St. Ambrose of Milan (c. 340–397 CE), utilized Cicero’s version of Natural Law to justify the emerging Christian Roman Empire. The concept largely disappeared, though, from philosophical—and what became theological—work for much of the Medieval Era, and was replaced by the Christian conception of Divine Law. Natural Law

would reemerge after the turn of the first millennium in the work of Master Gratian (c. twelfth century), and, most importantly, in the work of Saint Thomas Aquinas (c. 1225–1274). Thomas Aquinas synthesized Christian theology with rediscovered antiquarian texts, including those of the Stoics and Roman jurists. The result was the explicit reintroduction of Natural Law into Western philosophy, but in a way that accommodated the now-dominant moral conception of the Divine Law.

Thomas Aquinas redefined the ultimate universal law as the Eternal Law, from which derived both the Divine Law and the Natural Law. Bifurcating Divine Law and Natural Law would have profound implications for the development of modern political theory. On the one hand, the Divine Law was the universal moral foundation for personal salvation, as guided by the rules set forth in the Decalogue and in the commandments of the New Testament. The Divine Law applied to human-made law, according to Thomas Aquinas, but only insofar as political and legal rules affected a person’s ability to ascend to heaven. In this way, there was some overlap in the content of the Natural Law and the Divine Law.

On the other hand, Natural Law comprised abstract moral principles necessarily intrinsic in the temporal world and ascertainable by reason, and from these rational principles, people deduced proper socio-political rules. Natural Law was the universal moral foundation for human-made law. As Thomas Aquinas declared, quoting St. Augustine (354–430), “An unjust law is no law at all.”

This distinction between Divine Law and Natural Law matured in the seventeenth century in the work of Hugo Grotius (1583–1645), Samuel Pufendorf (1632–1694), and John Locke (1632–1704). It was now possible to provide reasoned analyses of the normative requirements of political systems and laws without reliance on particular, and most likely disputed, religious doctrine. Grotius, recognized as the “father of modern rights,” argued that Natural Law required respecting each individual’s life and liberty (*suum*) and property (*dominion*), which were identified as “Natural Rights.”

Our speculation has burst through the ramparts of heaven, not content to know merely what is shown to it. • Seneca (4 BCE–65 CE)

Pufendorf systematized Grotius's arguments, producing an original and intricate Natural Law/Natural Rights philosophy. His magnum opus, *On the Law of Nature and of Nations*, explained how Natural Rights justified civil society and its myriad legal rules; this text would serve as the principal legal treatise in Europe and would be often cited by English and American judges up through the late nineteenth century.

Finally, Locke's *Second Treatise on Civil Government* established Natural Law/Natural Rights theory as a normative foundation for limited, democratic government and the rule of law. Locke's political philosophy was the fountainhead for the Founding Fathers' creation of the United States of America.

Nineteenth and Twentieth Century Challenges

In the nineteenth century, Natural Law philosophy waned with the rise of utilitarianism and related positivist doctrines. Jeremy Bentham (1748–1832) famously declared that Natural Rights were “non-sense on stilts.” Legal positivism in particular directly challenged the central premise of Natural Law—the necessary connection between moral rules and socio-political rules. For legal positivists, such as John Austin (1790–1869 CE), legal rules can be analyzed and assessed without reference to, or reliance on, moral principles. The only law is human-made law, which is conceptually distinct from moral theory.

This raised questions about whether it was possible to form universal moral judgments about differing political systems or rules, which became a particularly salient concern with the rise of totalitarian regimes in the twentieth century. Following World War II, the Natural Law was called upon to condemn Nazi atrocities. Thus, in the second half of the twentieth century, there was a revival of scholarly interest in the Natural Law. Ronald Dworkin advanced the proposition of the inescapability of moral theory in legal decision making. John M. Finnis developed a version of Natural Law more closely aligned with the moral dictates of the Catholic Church, but other contemporary Natural Law scholars dispute his views

on these matters. As it has since the time of Cicero, Natural Law continues to offer universal, absolute moral rules for evaluating political institutions and human-made laws.

Law, Sacred

The term “sacred law” generally denotes a body of laws that is understood by a group of believers to have been divinely revealed. Most, but not all religions, have such legal aspects: Hinduism, for example, traces the origins of its sacred laws to the oral traditions recorded in the Vedas, while for Judaism the earliest source of sacred law is in the Torah.

Divine law usually refers to a divinely created natural law or to the unwritten and universal rules of morality, but sacred law is intended to govern human actions in the temporal sphere in accordance with the sacred, and often takes the form of positive written laws and oral or customary laws. Sacred law, therefore, leaves room for human interpretation and adjudication of conduct and transgressions of sacred law, usually by a priestly class. Although most, if not all, religions have legal aspects, this article will focus on the sacred laws of the major religions: Hinduism (and by extension Buddhism), Judaism, Islam, and Christianity—religions in which the law is believed to be divinely inspired or revealed, organized in a discernable collection of written or oral codes, and binding over human activities in the temporal sphere.

Hindu and Buddhist Law

Hinduism, the oldest of the major world religions, traces the origins of its sacred law to the earliest written texts, the Vedas, a collection of oral traditions written down in the period around 2000 BCE. Although the Vedas concentrated primarily on rituals devoted to a pantheon of gods, and not on law, the concept of dharmas, moral principles which guide

human action in conjunction with *karma* (the force generated by a person’s actions to bring about transmigration and to determine the nature of the person’s next existence), is discernable throughout. The dharmas also contributed to the development of the caste system of Hinduism, and thus formed a customary code of social obligations in ancient India.

Toward the end of the Vedic period, around 500 BCE, many of the rituals and rules that had developed from oral tradition were collected in texts known as sutras. The *Dharmasutras*, the rules of daily life, became the first codes of Hindu law. Living according to dharma became one of the “jewels” of Buddhism as well, and therefore, in terms of sacred law, Buddhism and Hinduism share a common origin. In Buddhism, however, the concept of dharma evolved aesthetically, with individuals seeking to achieve an inner tranquility, and it achieved its fullest expression in the Japanese cult of the Buddhist monk Nichiren (1222–1282 CE) and the Lotus school. In India, the Hindu law of dharma became a comprehensive code of personal law, governing marriage and the family, inheritance, and social obligations. In 1772, the British ordered that the *Dharmasutras* be considered binding as personal law in the Anglo-Indian courts, and thus the Hindu law, in conjunction with English rules of criminal and civil law, remained an effective code in a secularized form in the modern age.

Jewish Law

The Torah, also known as the Pentateuch, is the first source of sacred law for the Jewish tradition; it is a written, substantive law governing Jewish religious, social, and familial obligations believed to have been

divinely revealed to Moses during the Exodus from Egypt. During the fifth century BCE, after the Persian emperor Cyrus the Great (c. 550–529 BCE) permitted Jews to return to Palestine following the Babylonian conquest, a number of Jewish scribes provided commentaries on the Torah; some of the most significant are found in the Book of Ezra, and they created the foundations of a comprehensive Jewish jurisprudence. In addition to the Torah, Jewish tradition holds that the sacred law also included a divinely revealed oral law (*halakha*). *Halakha*, which was comprised of the statements of oral positive law (*Mishna*), commentaries on these laws (*Gemara*) and a number of moral and ethical precepts (*Haggadah*), were put into written form in the third through sixth centuries CE in the Palestinian and Babylonian Talmuds. The *Mishnas* are organized categorically and they cover legal matters ranging from religious observances to dietary laws, contracts and torts, criminal law, family law, and property and legal procedure. In the last few centuries BCE, legal questions turned into sectarian rivalries between the high priests, the Sadducees, who regarded only the Torah as authoritative, and the scribes and laity, the Pharisees, who regarded the oral law as an equal part of divine law. The activities of the Pharisees proved vitally important in Jewish history, as they developed a method of legal study of the law centered on a rabbinic tradition and scholarly communities that became a permanent feature of Judaism. Still, later movements in Jewish history, such as the Hasidic movement of the eighteenth century and the Jewish Enlightenment (*haskalah*) and secularizing reform movements of the late eighteenth and nineteenth centuries, have significantly challenged the binding authority of Jewish law to regulate the private and public lives of Jews.

Islamic Law

Islamic law (*sharia*) originated with divine revelation. The Qur'an, which Muslim tradition holds was divinely inspired, and which is generally believed to have been written by Muhammad (c. 570–632 CE), contains the founding principles of Islamic law,

principally, definitions of the holy obligations of believers. The Qur'an has few direct legal statements, and these are limited to modifications of Arabic customary law. However, once Muhammad had established an Islamic community at Medina in 622, he began to apply the general ethical and moral principles of Islam to matters of secular jurisprudence, thus forming a basis for a specifically Islamic customary law. The application of Qur'anic ethics to secular affairs developed into an Islamic jurisprudence, by which the juridical goal was the discovery of the exact meaning and application (*fiqh*) of Allah's law in secular matters. The founding of the first Islamic dynastic state, the Umayyad dynasty, in Damascus in 661 broadened the focus of Islamic law into areas of civil, commercial, and administrative law. The ninth-century Shafi'i school created a comprehensive Islamic jurisprudence that integrated elements of positive, customary, and natural law. Jurists were first obligated to consult the Qur'an and the precedents set by Muhammad on matters of law. In cases to which the positive law of the Qur'an did not directly apply, judges were then to compare elements of the case at hand with established precedent (customary law), and finally to take into consideration matters of public interest and equity (natural law). The Shafi'i school of Islamic jurisprudence became the dominant school of Islamic law, especially within the Sunni communities, and it generally fixed the available sources of law and juridical procedure. However, the Shi'a tradition, which became especially influential in modern-day Iran, held that secular rulers were divinely inspired descendants of Muhammad, and therefore their legal decisions established a much wider set of case law that jurists might examine for relevant precedents.

Christian Law

The early development of Christianity entailed a break with Judaism and Jewish law. Christian belief considered Jesus Christ the fulfillment of the Jewish prophets' prediction that a messiah would arrive. The mission of Paul (first century CE) to non-Jewish communities within the Roman world, and Paul's

insistence that converts to Christianity were not obligated to follow Jewish law, entailed a decisive break between Christianity and Judaism. Intermittent Roman persecution of Christianity in the first three centuries CE made the religion essentially a private cult, one which developed little in the way of laws that governed public life. The conversion of the Roman emperor Constantine (c. 274–337 CE) to Christianity, and the subsequent adoption of the religion as the official cult of the Roman Empire, meant that in secular legal matters, the Christian church deferred to the secular powers. The collapse of the Roman Empire in the West left the Christian church as one of the only central authorities in western Europe, yet it remained under the dominance of secular kings in legal and jurisdictional matters. The Investiture Controversy (1075–1122 CE) between the Holy Roman emperors Henry IV and Henry V and Pope Gregory VII, which started as a conflict over lay nomination of bishops, was as much a conflict about whether or not the state had jurisdiction over the affairs of the Church. The outcome decidedly favored the Church, and it emerged as an independent institution, a virtual state, with its own hierarchy and rules of governance. The Church created a system of canon law, the *jus novum*, which drew heavily from the Roman Code of the Byzantine emperor Justinian, which was newly discovered in the West. The monk Johannes Gratian (d. c. 1160 CE) drew up the full code of canon law, *A Concordance of Discordant Canons*, in 1140; although not formally a sacred law since it was not held to be divinely revealed, Christian canon law was the first widely used code of law in the West following the collapse of the Roman Empire.

Sacred Law and Integrative Jurisprudence

The modern trend by which in some societies the law is viewed as a fixed body of rules set by lawmakers acting out of secular and rational concerns, while in other societies the law continues to be understood as a function of the sacred, has led to what Samuel

P. Huntington (1996) called a “clash of civilizations.” Nonetheless, even various sacred law traditions contain elements of jurisprudence that would be recognizable to modern secular legal traditions. In other words, despite the fact that sacred law is held by believers to be divinely revealed, these sacred law traditions all contain elements of what the legal scholar Harold J. Berman (1993) called an integrative jurisprudence of positive law (the rules established by the law maker), customary law (the law in a historical and social dimension), and natural law (moral and ethical principles). Thus, the seeming dissonance between the various religious legal traditions, or between religious and secular law, may very well be overstated when considered in terms of common elements of integrative jurisprudence.

League of Nations

The League of Nations was created in the wake of World War I. It formally existed from 10 January 1920 until 1946, with its seat in Geneva (in neutral Switzerland). The league cannot be dissociated from the ravages of the Great War and the emergence of its conception as “the war to end all wars,” even though it totally failed in its goal of preventing the outbreak of another world war.

During the Paris Peace Conference, which was largely dominated by debate of Wilson’s Fourteen Points (delivered a year earlier to the U.S. Congress on 8 January 1918), the final draft of its Covenant (constitution) was agreed upon by the leaders of France, Great Britain, and the United States, known as the “Big Three” (Georges Clemenceau, David Lloyd George, and Woodrow Wilson), on 14 February 1919. The Covenant became part of the Treaty of Versailles (28 June 1919). Point 14 argued that “a general association of nations must be formed under specific covenants for the purpose of affording mutual guarantees of political independence and territorial integrity to great and small states alike.” Though European intellectuals had broached the idea of an international peacekeeping organization before the war, and a “League of Nations Society” was founded in Britain in 1915, the proposal has therefore remained associated with President Wilson.

The two great European victors, prime ministers Clemenceau and Lloyd George, had grave reservations, for different reasons. France would bow to the discipline of such an organization only if it felt safe against renewed German attack, and during the

discussions, Wilson persuaded Clemenceau that if he agreed to join in the creation of the League of Nations, the United States would guarantee the inviolability of France—and Lloyd George agreed to associate himself with the proposal. In Britain, the Conservatives, or the “party of empire,” as they liked to call themselves, were suspicious of this American idea, which might well be a ploy to sap Britain’s world role. Most important, Lloyd George had reservations about the proposed clause concerning sanctions by other League members if one member was attacked—the gist of what came to be known as collective security. Economic sanctions would penalize exporting countries like Britain, and military intervention would of necessity rely on the Great Powers’ involvement if it was to have any efficacy—which would also be onerous to Britain, with the largest navy in the world. Thus Britain would lose the freedom to make its own judgments and be automatically committed to costly measures possibly decided by others. But for President Wilson, this clause was the essence of the League—as indeed subsequent events were repeatedly to demonstrate—and Lloyd George relented, because he knew that this was the only way he could obtain reciprocal concessions from Wilson.

Much the same arguments on the loss of sovereignty to other (implicitly, lesser) nations were heard in the United States, especially in Republican circles, with their traditional isolationist desire to avoid entangling alliances. But Wilson refused to listen to these warnings, and despite the reluctant support of Clemenceau and Lloyd George, he was unable to persuade the United States Senate to provide the necessary two-thirds majority to ratify the Treaty on 29

The League of Nations in session in Geneva, Switzerland, 1936.
National Archives of Canada.

November 1919 (the vote was 49 for, 35 against). The League was mortally wounded, since its credibility and viability as an international peacekeeping force was seriously impaired, the more so as Bolshevik Russia had not been invited to join. Britain and France, both severely weakened by World War I, were left to provide leadership for an organization that never really managed to establish itself as an undisputed moral authority, let alone a respected military arbitration force.

The League had some success in settling minor border disputes between Bulgaria and Greece and Iraq and Turkey in the 1920s, but when it had to face its first major crisis involving two powerful members, the invasion of Manchuria, China, by the Japanese in September 1931, its impotence was made clear to all. Neither Britain, which had a wide but indefensible presence in South and Southeast Asia, nor the United States, which aspired to replace Britain as the major Western power in the area, was prepared to alienate the Japanese, who were allowed to keep the territories conquered by military force—the prevention of which was the *raison d'être* of the League. And when the League refused to recognize the new puppet state of Manchukuo, Japan resigned in protest (March

1933), thus setting a pattern followed by other unscrupulous states: aggression leading to purely verbal condemnation, seen as a pretext for withdrawal from the League.

Only a few weeks earlier, Hitler had become chancellor of Germany, which had been admitted in 1926. At the earliest opportunity, provided by the failure of the World Conference on Disarmament sponsored by the League, Nazi Germany left the organization, in October 1933. Italy followed suit in December 1937, after its invasion of Ethiopia and its easy defiance of sanctions imposed by the League. The Soviet Union, which had joined in 1934 because it feared Nazi Germany, was expelled in December 1939 after its invasion of Finland. The year 1940 marked the de facto demise of the League, even though it continued to exist de jure until its remaining economic and humanitarian activities were officially taken over by the new United Nations organization on 19 April 1946.

Leisure

The meaning of *leisure* has been difficult to pinpoint throughout history as cultures and technologies have changed, but is often defined in three categories: the possession of “free” or unobligated time, the participation in pursuits as varied as rest and outdoor recreation, and as a state of mind rather than a reflection of physical activity.

Leisure occupies a major role in the lives of many people. Its history, like that of most other things, activities, or concepts, depends on how it is defined. Leisure, however, has been particularly difficult to define for a variety of reasons. For one, it has been impossible to craft a definition that is both inclusive (i.e., all forms of leisure are included) and exclusive (i.e., everything that is not leisure is excluded). Moreover, few other languages around the world have a word with the same meaning as the English word *leisure*, making a cross-cultural understanding of the concept problematic. In North American and European leisure research, the term has been most often defined in three ways. First, leisure has been defined as free or unobligated time. Second, it has been defined as action or participation in “leisure activities.” Third, leisure has been defined as an experiential state of mind or being wherein meaning is the critical issue.

Leisure as Free Time

The idea that leisure as free time contributes to the development of civilization is central in the “surplus theory” of cultural evolution that developed in the

middle of the twentieth century. The U.S. anthropologist Franz Boas stated this thesis most clearly:

A surplus of food supply is liable to bring about an increase of leisure, which gives opportunities for occupations which are not absolutely necessary for the needs of life. In turn the increase of population and of leisure, which may be applied to new inventions, give rise to a greater food supply and to further increase in the amount of leisure, so that a cumulative effect results. (1940, 285)

But evidence accumulated since the late 1950s, initially based on studies of the Bushmen of the Kalahari Desert in southwest Africa, refutes the idea that food collectors have little or no free time compared to sedentary agriculturalists. The anthropologist Elman Service indicated that the Arunta, for example, an aboriginal hunter-gatherer group from Australia, have abundant free time, claiming that “The Arunta . . . are literally one of the most leisured people in the world” (1958, 10).

With the development of civilization, the amounts of free time, as well as its use, varied substantially between men and women and among social classes. In ancient Athens the leisure of upper-class males was supported by the labor of women, slaves, and working classes. In ancient Rome, public games, known as *ludi*, began during the third century BCE. The number of holidays increased rapidly with seventy-six celebrated by the first century BCE. By the fourth century CE, 175 holidays were devoted to theatrical performances, chariot races, and gladiatorial combats.

In post-Roman Europe, the agricultural cycle and the Roman Catholic Church largely dictated the free

Sixteenth-century German dancers are on their way a wedding feast.

time of commoners. Sundays and saints' days provided free time opportunities. Attempts to regulate working hours met with mixed results. A 1495 law in England prescribed a 5 A.M. to 7 P.M. working day, but ten- or ten-and-a-half-hour days were still common. Tradesmen often took an informal holiday on Mondays because raw materials were not delivered until late that day or the following morning, a practice that came to be known as "Saint Monday."

The Industrial Revolution, beginning in the mid-1700s in England, had the most important influence on the allocation of time to labor and leisure since the development of agriculture. It segmented days into specific periods of work time and leftover time through the imposition of "clock time" while factory work segmented families. Men, and frequently boys, left their homes to work in factories and mines while women and girls remained at home. Religious leaders often saw factory work as providing discipline and advocated long hours of work while recreation and play were devalued.

Hours of work declined only slowly from as many as eighty per week in early factories to fifty in much of Europe by 1847. The eight-hour day became widespread only after World War II. Although forty hours of work per week remains the legal standard in North America, France legislated the thirty-five-hour work week in 1998, and industry-employee-negotiated thirty-five-hour work weeks are common elsewhere in Europe. The vacation, another form of leisure as free and unobligated time, is also largely a product of the Industrial Revolution. Two weeks of vacation per year is typical in the United States. Chinese workers currently average about fifteen days of paid vacation per year, and Japanese workers twenty-five, while Europeans receive between four and six weeks per year.

How industrialization and technological change has influenced free-time availability is unresolved. In her 1991 book, *The Overworked American*, the economist Juliet Schor claimed that Americans are working longer hours since the 1960s because of employer demands coupled with employees' preference for more money rather than more free time. On the other hand, John C. Robinson and Geoffrey Godbey, in their 1997 book *Time for Life*, state that Americans have more free time than ever before, about five hours per week more than in the 1960s. The contrast between Schor's and Robinson and Godbey's results stems, at least in part, from the manner in which they gathered their data. Schor used aggregate work time estimates from the U.S. government and pollsters while Robinson and Godbey's data were based on time diaries kept by research respondents.

Leisure as Activity

The most common leisure activity for humans, both past and present, is undoubtedly resting or sleeping. The anthropologist Lauriston Sharp indicated that the Yir Yiront, an Australian Aboriginal tribe, devoted the majority of their leisure to rest:

Any leisure time the Yir Yiront might gain by using steel axes or other western tools was invested, not in

This Japanese picture scroll depicts a *bunraku* (puppet) show in the streets of Kyoto. The style of the calligraphy and brushwork suggest the scroll was made early in the Edo period (1600–1867).

“improving the conditions of life,” and certainly not in developing aesthetic activities, but in sleep, an art that they had thoroughly mastered. (1952, 82)

Socializing with family and friends surely occupied a major segment of the free time of members of early food-collecting societies. Games are ubiquitous in known human cultures, past and present, as well. Leisure in ancient Greece, albeit for male citizens, included Olympic sports, games, narrative and drama, art, debate, and contemplation. The Romans added several activities to those already practiced by the Greeks, such as gladiatorial combats, public baths, and the circus. The precursors to many modern games and sports were developed in central, south, and east Asia, such as chess (India), cards (China), and polo (Central Asia). Music, art, and poetry were popular pastimes for the elite classes in China and flourished during the Han (206 BCE–220 CE) and the Tang (618–907 CE) dynasties. Along with games, music, art, and forms of narrative, festivals provide recreation for individuals in both technologically simple and complex societies. Recreational drug use, especially alcohol, and recreational sex, including prostitution and varieties of pornography, have been common in most of human history.

In post-Roman Europe, between approximately 1000 and 1400 CE, leisure activities for nobility, clergy, freemen, serfs, and slaves were prescribed and proscribed by both secular and ecclesiastical authority. Hunting was popular with nobles but, when practiced by peasants, was often regarded as poaching and was strictly prohibited. Board games, such as chess, checkers (draughts), and backgammon were popular but gambling games, including dice and card games, were

frequently forbidden. Stylized war games in the form of tournaments were popular among upper classes while feasts, ball games, bull and bear baiting, dogfighting, and cockfighting were enjoyed by commoners. Alcohol lubricated much of leisure, especially for males.

Many entertainments, including music, minstrel shows, the circus, and theater became popular during the first half of the eighteenth century while participatory and professional sports flourished during the second half of the century. Increased financial means for workers combined with new modes of transportation, such as the train and streetcar, changed leisure in Europe and North America in the second half of the nineteenth century. These ushered in a commercialization of leisure, moving it from the home or local gathering places, such as the church or the pub, to the countryside, amusement parks, and resorts. The development of the automobile during the first third of the twentieth century further freed leisure seekers. The expansion of mass media such as newspapers, books, and magazines in the late nineteenth and early twentieth centuries, the introduction of movies in the early part of the twentieth century and commercial radio in the early 1920s, and the rapid development of television in the post-World War II era individualized and commercialized the leisure landscape. This trend has continued with the introduction of the personal computer in the late 1970s, publicly available services on the Internet in the mid-1980s, and the World Wide Web in the early 1990s. Computer games and Internet use, involving activities from shopping to pornography, are now both major leisure providers in the developed world and in urban areas in the developing world.

Women at a park in Beijing in 2003 participate in a group dance/exercise each day.

Leisure as a State of Mind

The meaning of leisure has depended on social status, broadly defined, in human groups throughout history. In technologically simple societies, and even in sedentary peasant communities, the most basic social divisions between males and females and adults and non-adults differentiate leisure in terms of time, activities, and meaning. Prior to industrialization and the institution of clock time, the separation, and therefore the meaning, of work and leisure was less distinct. For men, hunting was often arduous but also afforded excitement and companionship with peers. For women, food gathering and some kinds of chores included socializing with family and friends.

European societies largely define leisure in the context of events and eras such as the Renaissance, the Reformation, the Industrial Revolution, and, in more recent years, the rise of materialism and consumerism. The Renaissance, with beginnings in fourteenth-century Florence, Italy, was, in many ways, in contrast to Catholic theocracy. The Renaissance notion of secular humanism held that human beings, and their works, have intrinsic value, apart from their relationship to God. Hence, art, music, literature, and the events of daily life are important and meaningful, in and of themselves.

Reformation doctrine, under the influence of the theologian John Calvin, held that righteousness,

sobriety, faithfulness, self-discipline, and hard work were evidence of being in a state of grace while consumption and pleasure seeking were not. Hence, leisure is a lure to sin and a threat to righteousness. Calvinists attempted to suppress the festival calendar, sport, gambling, dancing, drinking, and other traditional recreations of European culture. Sixteenth-century Catholicism, in reaction, also tried to purge profane elements from the lives of church members. The pagan elements of carnival mocked Lent and, in 1562, the Council of Trent denounced the festivals and drunkenness associated with saints' days.

In England, under the influence of the Sabbatarian movement of the late sixteenth to mid-seventeenth centuries, saints' days were abolished, although Sunday was kept as a day of rest. "Blue laws" were introduced in England and America that prohibited numerous leisure activities, such as theater, as well as commercial transactions on Sundays. Remnants of blue laws, such as "dry" (i.e., no alcoholic beverages sold) townships or counties in some states in the United States, or the prohibition of certain kinds of commercial transactions (e.g., no Sunday auto sales in some states) still exist. While the Reformation and subsequent religious thought may have influenced leisure meanings, in many cases, traditional leisure pursuits simply were simply kept

out of the public eye as with the use of alcohol under Prohibition in the United States between 1920 and 1933.

Outlook for the Twenty-First Century

Changes in leisure since the Industrial Revolution have been driven by the combined influences of technological change, demographic change, and economic change. The digital video disk (DVD), the cell phone, now with the capacity to take and send photos, MP3 music players, and even space station vacations are recent examples of technological influences on leisure. While young people comprise major segments of populations in developing countries, the populations of developed nations are aging. Both the kinds of leisure available and the economic support for them must account for these differences. Leisure in many parts of the world will also be influenced by the rising status and economic power of women. With many national and local economies around the world depending on tourism, leisure travel will increase despite the recent threats imposed by terrorism. The same forces that determined leisure time, leisure activities, and leisure meanings in the past will continue to do so in the twenty-first century.

Lenin, Vladimir Ilyich

(1870–1924)

RUSSIAN REVOLUTIONARY LEADER

Vladimir Ilyich Lenin was the most important revolutionary of the twentieth century. His interpretations of Marxism led to the rise of Communism in the former Russian Empire and elsewhere. Lenin's experiment with socialism from 1918 to 1921, centralized economic institutions, party and state bureaucracies, and mechanisms of control influenced Stalin. The Soviet Union, founded in 1922, became a model for similar regimes.

Vladimir Ilyich Ulyanov, who under the pseudonym “Lenin” would become the most important revolutionary of the twentieth century, carried through the first enduring socialist revolution in world history in 1917. The establishment of a militant socialist regime in the vast territory of the former Russian Empire threatened all existing political and social systems. Lenin's successful combination of doctrinal nimbleness and tactical flexibility produced Leninism—the triumph of politics over spontaneous economic and social forces and the formation of a militant, party-led state controlled by a single leader. This became the foundation for the regime of Soviet leader Joseph Stalin as well as its offshoots and imitators during the Cold War.

Family Background

Vladimir Ilyich Ulyanov (1870–1924) was born in Simbirsk, Russia, to parents of multiethnic background. He was German, Swedish, and Jewish on his mother's side and Central Asian and possibly Russian on his father's. Two deaths in his family disrupted a fairly privileged and outwardly conventional childhood and

adolescence. His father, Ilya Nikolaevich Ulyanov, director of public schools in Simbirsk Province, died in January 1886. Alexander, Lenin's brilliant older brother, was hanged in May 1887 for his role in a terrorist conspiracy to assassinate Czar Alexander III. Vladimir was expelled from Kazan University in 1887, but received a law degree as an external student from St. Petersburg University in 1891. He quickly abandoned the law and instead became a dedicated follower of the German thinkers Karl Marx (1818–1883) and Friedrich Engels (1820–1895).

Revolutionary Career

Lenin departed from Marxian theory, which in its most basic form posited that the revolutionary consciousness of the industrial proletariat would spontaneously produce socialist revolutions against capitalism. Lenin, however, believed that by themselves the workers could not achieve socialist consciousness. The working class in his view needed to be organized by a party led by scientific socialists. In 1903, Lenin's position split Russia's Social Democratic Party, but he won ground against the opposing Menshevik faction of that party and maintained personal control over his Bolshevik faction between 1903 and 1917. Lenin continually amended his original position to exploit revolutionary opportunities, and his tracts had vast influence.

Like other Russian revolutionary leaders in the early twentieth century, Lenin lived in exile for long periods of time (in Siberia from 1897 to 1900 and in western Europe for most of the years between 1900 and 1917). With German support, he returned to Russia after the collapse of the Romanov regime

A lie told often enough becomes the truth. • Vladimir Ilyich Lenin (1870–1924)

in March 1917. Lenin believed that World War I (1914–1918) was a symptom of capitalism’s final crisis and that a Russian socialist revolution would spark similar revolutions in Europe. Faced with the dual power of Russia’s Provisional Government and soviets (mainly urban-based revolutionary councils), Lenin called for all power to go to the soviets. In November 1917, Lenin’s Bolsheviks, led by Communist leader Leon Trotsky under the aegis of the Petrograd Soviet, overthrew the Provisional Government. At the Second Congress of Soviets, which was convened during the assault on the Provisional Government, Lenin established the de facto dictatorship of his party. He became the chair of the Council of People’s Commissars, and he retained that post as well as leadership of his party (renamed the Communist Party in 1918) until his incapacitation in 1923.

In Power

In January 1918, Lenin ordered the dissolution of the democratically elected Constituent Assembly. A civil war followed, but Lenin’s astute policies, his opponents’ obtuseness, and a great deal of luck saved the revolutionary regime. Distribution of land to the peasants and control of the central industrial region had given the new regime a basic advantage. After withdrawal from World War I followed by the Treaty of Brest Litovsk with the Central Powers (Austria-Hungary, Bulgaria, Germany, and Turkey) in March 1918, Lenin dealt with his domestic opponents. The defeat of the Central Powers allowed him to recoup most of the losses incurred at Brest Litovsk; war weariness and mutinous troops weakened the ability of Lenin’s foreign opponents to intervene in the civil war. To Lenin’s disappointment, however, European troop mutinies and minor outbreaks of soviets did not yield socialist revolutions in Europe. Lenin’s Third International of 1919, an association of international Communist parties later called the Comintern, became an instrument of Soviet policy and a stimulus to right-wing reaction in Europe. In recognition of the power of nationalism, Lenin created in 1922 the framework for a multinational federation, the Union

of Soviet Socialist Republics, or Soviet Union. In the long run, however, nationalism led to the collapse of the Soviet Union in 1991.

Lenin’s Last Experiments

During the civil war of 1918–1921, Lenin’s regime experimented with a fully socialized and centralized urban-industrial economy called “War Communism.” It destroyed the money economy and stimulated the underground markets that became a chronic feature of the Soviet command economy. Grain requisitioning alienated the peasants. At the end of the war, the industrial sector lay in ruins, urban centers were depopulated, the peasantry suffered devastating famine, and the Communist Party faced mutinous sailors and urban strikes. Lenin had by that time established a strong party-based bureaucracy, the large Red Army, and a powerful political police (*Cheka*). During 1918–1922, Lenin defeated not only the Whites (anti-Communist forces), but also suppressed the Russian Orthodox Church; other socialist parties; Trotsky’s faction; the syndicalist wing of his party that desired worker control of the economy; a large-scale peasant rebellion; and the mutiny of Russia’s Kronstadt naval base. At that point, Lenin abandoned War Communism and its policy of grain requisitioning and created a system of taxation and markets in which the peasants might trade their surplus. The New Economic Policy (NEP) of 1921 restored a money economy and revived urban retail trade and small industrial enterprises. Lenin encouraged investment by foreign capitalists, with minor results. He left to his successors the task of modernizing the economy. Although NEP created a framework for exchange between the urban-industrial and village-agricultural sectors, it did not solve the problem of backward, small-scale peasant agriculture. Lenin was still rethinking Russia’s path to socialism when he suffered a series of strokes from 1922 to 1924, the fatal one in January 1924. In 1922, Lenin supported Stalin’s promotion to the post of general secretary of the Central Committee of the Communist Party, which would ensure Stalin’s rise to power after Lenin’s death.

Vladimir Ilyich Lenin, circa 1920. Lenin combined doctrinal nimbleness and tactical flexibility to form a militant, party-led state under his control. Library of Congress.

The period after World War I showed that nationalism remained more powerful than international socialism. The international situation did not allow the Communists during Lenin's lifetime to export their

revolution, but Lenin's abandoned experiment with War Communism from 1918 to 1921 became the basic economic model for Stalin's and other Communist regimes. Lenin might have done things differently than Stalin had he lived, but Stalin quite rightly pointed to Lenin as his mentor. Political control trumped everything else, and personal control eventually subordinated the leadership of the party-state to the whims of dictators. The post-Stalin Soviet leaders rejected Stalin's extreme methods and tried to revive Lenin's NEP. Lenin remained the Soviet regime's basic source of legitimacy until its collapse in 1991.

Leonardo da Vinci, one of the universal geniuses of Western history, made contributions to art, mathematics, and science that anticipated the ideas and inventions of future centuries. Most significantly for world history, Leonardo's curiosity and his belief in the power of observation spurred him to investigate and record the forces that drive the natural universe and define man's place within it.

A true "Renaissance man," Leonardo da Vinci achieved renown in painting, architecture, engineering, science, and anatomy. He was born in the Tuscan countryside, the illegitimate son of a notary, and trained in the Florentine workshop of Andrea del Verrocchio (1435–1488). By 1472 he was recorded as member of the guild of painters in his own right, and evidence of his growing reputation began to build. Works from this early period include the *Adoration of the Magi* (1481–1482), a painting left unfinished, as were so many of Leonardo's projects.

In 1482 or 1483 Leonardo left Florence for Milan to serve in the court of Duke Lodovico Sforza (1452–1508). His duties at the court were wide and included not only painting, sculpture, and architecture, but also military and civil engineering, stage design, and interior decoration. The life of a courtier allowed Leonardo time to pursue his interests in the natural world and mathematics. His notebooks, kept throughout his life and written in mirror writing, reflect his wide-ranging interests. Studies of human anatomy, wind and water, plants and animals, machines, and optics occupied his restless mind. Heavily illustrated, these notebooks constitute a document of

Leonardo's curiosity and his ingenious investigation of mysteries such as flight.

In addition to creating some of his most famous paintings during this period—for example, *The Last Supper* (1495–1497) in Santa Maria delle Grazie—Leonardo worked to fulfill the commissions provided by his master, such as an enormous bronze horse honoring Lodovico's father, Francesco

Leonardo da Vinci, *Self-portrait*. National Gallery, Turin, Italy.

Anyone who conducts an argument by appealing to authority is not using his intelligence; he is just using his memory. • Leonardo da Vinci (1452–1519)

Sforza. Although Leonardo managed to produce a clay model, the horse was never cast; Milan fell to King Louis XII of France in 1499, and Leonardo fled the city.

He accepted in 1502 a position as military engineer for the infamous Cesare Borgia (c. 1475–1507), but his hopes for Borgia patronage did not fully materialize, and Leonardo returned to Florence. There

Leonardo da Vinci, *Assault Chariot with Scythes* (n.d.). Charcoal drawing. National Gallery, Turin.

he perfected his *sfumato* style (subtly shaded figures blending into the composition) in his *Virgin, Child and St Anne* (begun in 1502 but not completed until 1516), and attempted a new fresco technique for *The Battle of Anghiari* (1502–1503), commissioned for the Hall of the Great Council, the central deliberative chamber of the Florentine Republic. Unfortunately, the work is altogether lost as his experimental technique failed: the plaster did not dry evenly and the paint did not adhere.

Leonardo's second residence in Florence was consequently not very productive, although he did begin the portrait that would become perhaps the most famous painting in the world, the *Mona Lisa* (1503–1506). Returning to Milan in 1508, Leonardo resumed his responsibilities at court, but this time for the French, who were masters of the city until 1512, when the Sforza dynasty briefly returned. Again, most of his artistic projects were never carried to fruition (an exception is his *Virgin of the Rocks*, 1503–1506), in part because of his growing interest in scientific pursuits, especially anatomy.

In 1513 Leonardo set out for Rome. He served the Medici family, who had returned as rulers of Florence in 1512, including the head of the family, Pope Leo X. It is probable that Leonardo accompanied Leo to Bologna to meet with King Francis I of France. The young king recognized Leonardo's genius and convinced him to come to France in late 1516 or 1517, where Leonardo was presented with a small chateau at Cloux (Clos-Lucé), near the king's residence at Amboise. Leonardo continued his theoretical work and engaged in specific commissions for Francis, including

designs for elaborate entertainments and grand royal palaces (which were never built). He also completed some of the unfinished paintings he had brought with

Leonardo da Vinci. *Virgin of the Rocks* (1506). Oil on wood. National Gallery, London.

Leonardo da Vinci, *Last Supper* (1498). Fresco. “Restorations” made to Leonardo’s frescos over the years often obscured the artist’s original intention. In 1997 scientific treatment to the *Last Supper* revealed that a platter on the table, long thought to contain bread, actually held grilled eel and orange slices. Judeo-Christian iconography provides no evidence that eels were served at religious feasts, but the dish was a popular delicacy during Renaissance Italy.

him. Leonardo’s health had already begun to decline, perhaps the result of a stroke; in August 1519 he was dead, and was buried in Amboise.

The contribution of Leonardo to the culture of the West was enormous. His wide-ranging genius united many aspects of technical and creative skill (such as designs for a parachute and flying machines) to establish new heights of High Renaissance art; indeed, the art historian Giorgio Vasari (1511–1574) saw in Leonardo the moment when the ancients were at last surpassed. Most significantly for world history, Leonardo believed in the power of human observation. His curiosity about nature and the world spurred him to investigate and record the forces that drive the natural universe and define man’s place within it.

Letters and Correspondence

From its proliferation in the second millennium BCE, when paper-like materials made written communication more feasible, correspondence served both a political and a socioeconomic function, asserting authority but also representing personal emotions and attitudes of the author. As the world becomes increasingly interconnected via technologies, written communication continues to change both in speed and fluency.

Correspondence, the process by which people communicate over distance, is intricately connected to the technology of writing, which emerged 5,000 to 7,000 years ago. Written correspondence marked a transition from oral communication as civilizations became more complex and permanent records of transactions became increasingly necessary.

Political and Social Functions

Writing systems existed by around 3000 BCE, but mobile written communication only became practical in roughly 1200 BCE when papyrus, bamboo, silk, and other types of paper-like materials replaced bone, shells, and stone, most of which were controlled by elites.

The Chinese development of paper by the second century CE facilitated communication for commoners, especially for sending ritual messages venerating familial ancestors. Because paper was cheaper than silk or bamboo, more people could write letters, and its function expanded beyond a merely economic or political role. Outside China, correspondence continued

to be written on more expensive material such as parchment, which increasingly replaced papyrus after the eighth century CE. In Mesoamerica, correspondence, also written on animal hides, often showed the genealogies of dynasties, the boundaries of power, and social contracts. Globally, then, technological changes created practical and mobile mechanisms of communication across long distances.

Before this, official correspondence was the primary form of written communication in societies. Thus, the political form of correspondence preceded the social function usually ascribed to letters, serving as a way for leaders to correspond with their subjects by delegating laws and responsibilities. But it also served as a means of diplomatic exchange to solidify alliances, establish economic contact, or deal with conflicts.

Correspondence and Cultural Contact

Another important function of correspondence is the exchange of ideas and knowledge across cultural boundaries. The Islamic world, for example, maintained communication throughout the vast kingdoms through the narratives of travelers like Ibn Battuta (1304–1368 or 1369 CE), who discussed his encounters with Muslim communities in Africa. Ibn Battuta's travels, like Marco Polo's (1254–1324 CE) to China, provided readers with cultural descriptions of other regions, and were important elements of cultural contact in a growing world network.

In addition, the spread of paper from China to Southwest Asia to Europe in the first millennium CE further transformed the nature of communication

The hour of my death draweth fast on, and my case being such, the tender love I owe you forceth me, with a few words, to put you in remembrance of the health and safeguard of your soul . . . • **Catherine of Aragon (1485–1586), letter to Henry VIII**

between peoples. As printing became more mechanized, rapid diffusion of texts enabled writers to reach larger audiences. The development of the newspaper and political pamphlet, both forms of public correspondence, was only possible because of the emergence of Chinese block printing during the Tang dynasty (618–907 CE), and the subsequent emergence of the printing press in Europe around 1450 CE. Once people gained access to public forums, letters and pamphlets encouraged political and social confrontation. As an example, Martin Luther (1483–1546 CE) wrote public letters to the German nobility soliciting their support against papal authority; his writings challenged political and religious alliances throughout Europe and helped launch the Protestant Reformation.

Class and Gender

Throughout this period, however, letter writing remained confined to a relatively small portion of any given population, though the changing technologies incorporated more classes of people. As early as the eleventh century CE, manuals emerged in Europe that taught people correspondence skills. By the eighteenth century, autodidactic manuals were fairly widespread and cultivated business and social writing as well as accounting skills designed to facilitate correspondence between business owners and their clientele. Similar types of manuals emerged toward the end of the Ming dynasty in China (1368–1644 CE).

Especially important in the social function of correspondence was the uniform inclusion of women. Women's roles as letter writers are occasionally described as autobiographical, but women's letters equally portrayed knowledge of political affairs, frequently listed business transactions, or subtly undercut perceived social roles. In China, the historian Ban Zhao (45–116 CE) wrote a tract for her daughters on proper feminine behavior in a patriarchal society. The family letters of the English matriarch Margaret Paston (d. 1484) reflect her belief in the importance of

letter writing as a form of power and persuasion in medieval England.

Nineteenth and Twentieth Centuries

Correspondence became more widespread in the nineteenth century as education globally became more accessible and as postage, paper, and writing utensils became less expensive. In so-called semiliterate societies, where the practice of writing maintains connections to oral traditions, letters were not so much private affairs, but very public forums of communication. For example, into the late twentieth century in the Sudan, a letter between family members was often transcribed in public; once received, someone who could read then conveyed its contents in a public space. In this way, the community kept abreast of familial issues, and oral and written traditions remained balanced. Another example is twentieth-century Polynesia, where people managed family affairs and conducted business via letters after the introduction of writing.

Finally, in regions where writing systems had been co-opted or transformed (such as the Yucatan Peninsula or South Asia), letters—both public and private—served as venues for social conflict. During the British Raj in India (1858–1947), for example, Indians vocalized their discontent with internal affairs or imperial policy through their access to public correspondence in newspapers. Thus, written correspondence served not only the elite; subordinate groups and classes utilized the same technologies to challenge the system.

Twenty-First-Century Trends

As the world becomes increasingly interconnected via technologies such as e-mail, text messages, or facsimiles, written communication continues to change both in speed and fluency. On the one hand, it is becoming increasingly democratic, with the Internet fostering instant global communication. On the other hand, it is also subject to potentially insidious

effects as seemingly very personal letters are capable of being sent to mass recipients for financial or other gain. In both cases, just as with the emergence of the first written symbols, technology continues to shape and restructure the way in which humans correspond both within and between communities.

Liberalism

The term *liberalism* has been used throughout history in political, cultural, and economic contexts to describe widely juxtaposed positions. Its etymology (derived from the Latin word *liber*, meaning “free”) leaves it further open to ambiguity. After 1945 the term *liberalism* lost whatever coherence it had garnered over time, and toward the end of the twentieth century *liberalism* became virtually a term of opprobrium.

Liberalism is probably the most elusive concept in the modern world’s repertory of political philosophy. It has been used to describe a panoply of antithetical positions, ranging from left to center to right in the political spectrum, and referring primarily for some to the economic arena, for others to the political arena, and for still others to the cultural arena. There is consequently no single correct meaning for the term, but rather a series of meanings, each of which has to be situated historically in its location and evolution.

Liberalism is etymologically derived from the Latin word *liber*, which means “free.” But free from what and from whom? Or is it rather, free to do something, and then what and to whom? For the Romans *liber* was the opposite of *servus*, therefore free from a subordinate status. As an adjective with political connotations, the term *liberal* seems to have been first used in France during the years of the Directory (the five-man legislature in the late 1790s). The historian Cruz Seaone (1968, 157) attributes the term’s first use most likely to Benjamin Constant in 1796 speaking of “liberal ideas.” The French linguist Ferdinand Brunot (1937, 660–661) starts its career in Year VIII (1797–1798) as a term opposed to “sectarian” and “Jacobin.”

Linguists and historians alike seem to agree that the adjective became a noun in Cádiz in 1810–1811, when it was applied to a group of the Spanish Cortés. A member of the Cortés, the Conde de Toreno, writing some sixty years later, says that the public described the “friends of reform” as *los liberales* (cited by Marichal 1955). J. H. Billington (1980, 554, n. 33) says this led to the creation of a *partido liberal* in 1813 (see also Cruz Seaone 1968, 158). D. J. Manning (1976, 9) claims that “the original implications of the term liberal were for the most part derogatory.” But this is not at all clear from the description of the Cortés. It comes into French and British political usage in 1819 (see Bertier de Sauvigny 1970, 155; Halévy 1949, 81, n.3), but it will be another quarter century before the Whigs become the Liberal Party.

The next stage in the story was the construction of liberalism, which defined itself as the opposite of conservatism, on the basis of what might be called a “consciousness of being modern” (Minogue 1963, 3). Liberalism always situated itself in the center of the political arena, proclaiming itself to be universalist. Sure of themselves and of the truth of this new worldview of modernity, liberals sought to propagate their views and intrude its logic within all social institutions, thereby ridding the world of the “irrational” leftovers of the past. To do this, they had to fight conservative ideologues whom they saw as obsessed with fear of “free men,” men liberated from the false idols of tradition. In other words liberals believed that progress, even though it was inevitable, could not be achieved without some human effort, without a political program. Liberal ideology was thus the belief that, in order that history follow its natural course, it was necessary to engage in conscious, continual,

intelligent reformism, in full awareness that “time was the universal friend, which would inevitably bring greater happiness to ever greater numbers” (Schapiro 1949, 13).

Liberalism as an ideology, as opposed to liberalism as a political philosophy—that is, liberalism as a metastrategy vis-à-vis the demands of popular sovereignty as opposed to liberalism as a metaphysics of the good society—was not born adult out of the head of Zeus. It was molded by multiple, often contrary, interests. To this day the term evokes quite varied resonances. There is the classic “confusion” between so-called economic and so-called political liberalism. There is also the liberalism of social behavior, sometimes called libertarianism. This *mélange*, this “confusion,” has served liberal ideology well, enabling it to secure maximal support. Liberalism started ideological life on the left of the political spectrum, or at least on the center-left. It presented itself as the opponent of the conservative thrust after 1815, and as such it was considered by conservatives to be “Jacobinical” (Rémond 1982, 16). But as liberalism gained momentum, support, and authority as an ideology, its left credentials weakened; in some respects it even gained right credentials. But its destiny was to assert that it was located in the center. It was thus conceived in the eighteenth century by Constant, who considered it “a ‘moderate’ and ‘central’ position between the two extremes of Jacobinism (or ‘anarchy’) and Monarchism (‘the fanatics’)” (Marichal 1956, 293). It was thus institutionalized in the liberal parties of the nineteenth century and celebrated by Schlesinger (1962) in the twentieth century as the “vital center.” At all these times, liberals claimed the position between the conservatives or the right, those who wanted to slow down the pace of normal change as much as possible, and those (variously called democrats, radicals, socialists, or revolutionaries) who wanted to speed it up as much as possible. In short liberals were those who wished to control the rate of change such that it occurred at what they considered to be an optimal pace.

The two emblematic figures in the development of this metastrategy were François Guizot and Jeremy Bentham. Guizot was a historian, a man of letters,

and of course a politician. Bentham was a philosopher and an advocate of concrete legislative action. In the end the eyes of both were focused on the state. Guizot defined modernity as “the substitution in government of intellectual means for material means, of ruse for force, Italian politics for feudal politics” (1985, 243; see Rosanvallon 1985, 223–230). He sought a way to mute popular sovereignty without returning to the divine right of kings. He found it by claiming the existence of an “irresistible hand” of reason progressing through history. By arguing this more political version of the Smithian “invisible hand,” Guizot could establish as a prior condition for the exercise of the right to popular sovereignty the possession of “capacity,” defined as the “faculty of acting according to reason” (Rosanvallon 1985, 91, 95). Only if suffrage were limited to those having this capacity would it be possible to have a “scientific policy” and a “rational government.” And only such a government would eliminate the triple menace of “the return of arbitrary government, the unloosing of popular passions, and social dissolution” (Rosanvallon 1985, 255–256; see also 156–158).

Guizot’s reputation was to fade, but Bentham’s reputation as Great Britain’s quintessential liberal has never ceased to be asserted. The French historian and philosopher Elie Halévy pointed out that Bentham took a starting point not too different from that of Rousseau but had it end up not with revolution but with classic liberalism:

Each individual is the best judge of his own interests. Hence we ought to eliminate all artificial barriers which traditional institutions erected between individuals, all social constraints founded upon the presumed need to protect individuals against each other and against themselves. An emancipatory philosophy very different in its inspiration and in its principles but close in many of its practical applications to the sentimental philosophy of J.-J. Rousseau. The philosophy of the rights of man would culminate, on the Continent, in the Revolution of 1848; the philosophy of the identity of interests in England in the same period in the triumph of Manchesterian free trade concepts. (Halévy 1900, iii–iv)

Liberalism is trust of the people tempered by prudence. Conservatism is distrust of the people tempered by fear. • **William E. Gladstone (1809–1898)**

On the one hand, for Bentham society was the “spontaneous product” of the wills of its individual members, and therefore “a free growth in which the state could have no part.” But at the very same time, and this is crucial for Bentham and for liberalism, society was “the creation of the legislator, the offspring of positive law.” State action was therefore perfectly legitimate, “provided the state was a democratic state and expressed the will of the greatest number” (Halévy 1950, 332).

We come here to the heart of the question. Was liberalism ever a metastrategy of antistatism, or even of the so-called night watchman state? One must distinguish between the text of laissez-faire and individual rights that constitute the public ideals of liberalism and the subtext of a metastrategy to regulate the pace of change in the modern world. Neither the Utilitarians nor subsequent versions of liberals found laissez-faire or individualism and state intervention in contradiction one to the other. In De Ruggiero's words (1959, 99) projects of legislative reform were seen to be “a necessary complement” to the principles of individualism.

In the beginning of the twentieth century, the Home University Library commissioned three short volumes, one on each of the three great ideologies: conservatism, liberalism, and socialism. In the small book on liberalism, L. T. Hobhouse summed up what he called “the heart of liberalism” as follows:

[L]iberty is no mere formula of law, or the restriction of law. There may be a tyranny of custom, a tyranny of opinion, even a tyranny of circumstance, as real as any tyranny of government and more pervasive.

[F]reedom is only one side of social life. Mutual aid is no less important than mutual forbearance, the theory of collective action no less fundamental than the theory of personal freedom. (1994, 56, 59–60)

After 1945 the term *liberalism* lost whatever coherence it had had before then. In the United States it was used to emphasize the component of reformist

action, and toward the end of the twentieth century became virtually a term of opprobrium. In Great Britain and some Commonwealth countries, it retained its quality of centrism. And in many countries of continental Europe, liberal parties emphasized economic conservatism (but were secularist).

In the 1980s a new term, *neoliberalism*, came into common vocabulary. Neoliberalism seemed to mean primarily an emphasis on laissez-faire, a distinct distancing of its advocates from any association with social reformism. It seemed indeed to be an ideology largely advocated by conservatives, albeit without the historical emphasis of conservatives on the importance of traditional authorities (and mores).

While liberalism could be considered to be the dominant ideology of the world-system in the second half of the nineteenth century and the first half of the twentieth, by the beginning of the twenty-first century, liberalism seemed to have become very much a minority point of view besieged on all sides.

Libraries

Libraries contribute significantly to the advancement of civilization. Since humans began to record ideas and information for later recall, collections of records kept throughout the world for five thousand years, consisting of a few items or millions, have been important in preserving the memory of society. Although each period and locality is distinct, many issues of record keeping, such as preservation and classification, are the same.

Libraries are collections of graphic records, organized for accessibility and maintained for the benefit of individuals in the community they serve. Libraries generally consist of portable physical entities (books) made of durable materials that contain written and artistic notations of reasonable length. The standard unit in libraries has been called the “generic book” because through the millennia it has utilized various materials—bones, skins, clay, bamboo, papyrus, paper, magnetic tapes, and plastic—and taken many forms—tablets, rolls, codices, reels, and disks. When collections consist primarily of records of institutions and individuals that are organically related—that is, they share a common creator, subject or purpose, as opposed to isolated, random artifacts—and maintained for access because of their continuing value, they are referred to as archives. When they consist of creative texts dealing with cultural and historical themes, they are called libraries.

After human beings began to speak, the need arose to preserve orally transmitted information. Although visible marks of any kind could record some ideas, in order to transmit information reliably from one generation to another and ultimately from one culture

and era to another, a system needed to be developed whereby those marks would be conventional enough to convey complex ideas over time—that is, the marks needed to be somewhat standardized in order to be understood by others. After several centuries of experimentation with pictographic symbols and multishaped tokens and their representations, writing appeared in both Mesopotamia and Egypt sometime before about 3000 BCE.

Ancient Libraries

Early collections of a few clay tablets or papyrus rolls were likely to be primarily archival repositories, but within centuries, books that included religious, historical, literary, and scientific texts appeared and true libraries began, often in conjunction with archives. Many early library collections were housed in temples, where scribes produced and maintained them. These temple libraries were established throughout the Fertile Crescent and in Egypt, India, and China. Caretakers of these collections were faced with problems of preservation, classification, and physical arrangement.

Among the oldest library archives is the collection at Ebla, a city in northwestern Syria dating to at least the middle of the third millennium BCE, which contained more than fifteen thousand tablets, including a variety of archival records, as well as linguistic reference works, chronologies, gazetteers, manuals dealing with the physical world, and religious and literary works. Similar repositories existed at Mari in northwestern Iraq and Boghazkoy in modern Turkey. Though the physical evidence is not as abundant in Egypt, archival collections also appeared there during

this period, according to inscriptions on temple walls and surviving scrolls. While small collections were found throughout the Fertile Crescent, the library of the Assyrian Assurbanipal reached its peak in Nineveh in northern Iraq in the seventh century BCE. Although the library was buried in the destruction of the Babylonians in 612 BCE, the British excavated it in the nineteenth century and much of the collection is now in the British Museum.

Evidence exists that the Mycenaean civilization of the late second century BCE was the heir of developing library processes and technology, but it was only after about 600 BCE that Greek libraries and archival repositories become common. Focusing on epics composed much earlier, by the sixth century BCE the movement toward wider reading and collecting was well underway. In the late fourth century BCE, Hellenic civilization promoted broader inquiry and utilization of the written word, which resulted in a rising volume of both scholarly and popular works. The great Alexandrian Library in Egypt, founded about 300 BCE, became a repository for materials from all over the known world and was a center for scholarship and original research. Along with smaller libraries at Pergamon and Athens, it would continue these functions for several centuries, until its decline in the fourth to seventh centuries CE.

As heir to the Greek tradition, Rome recognized the value of the library, and through confiscated books and new copying began to build libraries of its own. The emperors Augustus, Tiberius, Vespasian, Trajan, and Hadrian established libraries in Rome in the first and second centuries CE. These collections at Rome, which typically contained separate rooms for Greek and Latin books, and similar ones in the provinces, were housed in temple-like buildings and later in public baths. They were widely used and considered symbols of civilization.

During the early centuries of the current era, the form of the book changed from the scroll (or roll) to the codex, the form of book we know today. This change in format enabled texts of greater length to be bound together as a unit, enhancing portability and ease of use. During this period, recognized

collections of writings developed, including major works of mythology, history, philosophy, and religion. (For example, the Bible of the Christians, consisting of approximately sixty-six books, written over a period of more than a millennium, assumed its form during this period and was itself a kind of library.) Christian libraries, such as the one at Caesarea in Palestine (c. 200–c. 800), provided major repositories for theological and historical writings.

The weakening of central imperial authority and barbarian threats, as well as the rise of organized Christianity and the early monastic movement, brought challenges and changes to the cultural environment of the late Roman Empire. The decentralization of control and influence encouraged local manifestations of governmental and church institutions, including libraries, which spread to the farthest reaches of the empire. After about 600, when in the Western portion of the empire the church had assumed many of the stabilizing institutions of society, scholarly efforts centered largely on preserving old texts and keeping existing learning alive by writing texts. Libraries continued to flourish at Constantinople in patriarchal and academic libraries until the fifteenth century.

In Asia, books and libraries grew in significance in the period of antiquity. The Aryans, who brought Vedic traditions to South Asia about 1500 BCE, supplanted the Harappan culture already established in the Indus Valley. They in turn provided the environment for the rise of Jainism and Buddhism in the sixth century BCE—each religious tradition also developed its own canon of religious writings. Like Judaism and Christianity, which took root in the centuries spanning the divide of the eras BCE and CE, Jainism and Buddhism had significant written literature. Their extensive texts joined a developing archival system to produce library collections maintained by individual societies. The experience of the Han dynasty in China (206 BCE–220 CE) with the expansion of Buddhism was in some ways similar to the challenge posed to the later Roman Empire by the expansion of Christianity with respect to the consolidation of governmental authority and the preservation of cultural heritage. In particular, the Han dynasty experienced

the proliferation of Buddhist texts, sometimes without official sanction. Meanwhile, Han emperors encouraged the compilation and editing of Confucian writings and a variety of other texts, including those in the arts and sciences, as well as the maintenance of such collections. The invention of paper and the extensive use of block printing in this period also expanded the production of books and increased the number of collections available to governmental and cultural institutions, and to individuals. These works were frequently copied and collections were maintained in monasteries and other protected sites. The Cave of a Thousand Buddhas near Dunhuang in Chinese Turkestan housed one such collection, which had been developed about 1035 and was discovered as recently as 1907. This famous cache of texts was collected in the years prior to the cave being sealed, about 1035, which invaders threatened. It was discovered by the British archaeologist Aurel Stein and was dispersed to several repositories in Asia and Europe. Eventually massive collections of these works were reproduced by Chinese imperial authorities for access and for preservation. Two major hand-written encyclopedias were produced—one between 1403 and 1408 (more than eleven thousand volumes) and another between 1736 and 1795 (thirty-six thousand volumes). The latter was produced in seven copies of which two are still largely extant. (The works not selected for inclusion were subsequently lost to succeeding generations.) The writings of Confucius, Buddha, and their followers were brought to Japan and Korea in the sixth and seventh centuries CE, and schools, books, and libraries soon followed.

Medieval Libraries

While the arts of publishing flourished in Asia and monks and court officials preserved materials as best they could in Europe, the rise of Islam, beginning in the seventh century, formed a link between East and West through its growing network of scholarship and commerce. The librarians and bibliographers of this period began to promote a cross-pollination of cultures, languages, and traditions.

A public library in a Spanish colonial building in Guadalajara, Mexico, in 2003.

As Muslims translated Greek and Latin manuscripts into Arabic and produced their own literature, they also soon introduced papermaking from China across their domain to Andalusian Spain. By the ninth and tenth centuries major urban centers like Baghdad and Cairo enjoyed numerous libraries—many of which were open to the public—that supported institutions of learning culture such as schools, mosques, and palaces. By searching existing collections and employing copyists and binders, Caliph al-Hakim II (961–976), for example, built an extraordinary library in Cordoba with about 400,000 volumes—the catalogue itself consumed forty-four volumes. Some scholars suggest that the intellectual activity in the great mosque in Cordoba, which attracted scholars and students from across the Near East and Western Europe, served as a catalyst for the establishment of new universities and the transmission of important knowledge from East to West—of papermaking, for example. During the twelfth and thirteenth centuries and afterward, warfare from within the Islamic regions and from invaders resulted in the decline and loss of many of

the great collections. In many cases only individual items have survived. The barbarian invasions of the Roman Empire, including Rome itself, in the fifth and sixth centuries, had different results in the East and the West. In the region governed by Constantinople (Byzantium, today Istanbul) the institutions of state and church, drawing on Greek cultural foundations, continued relatively intact until the coming of the Persian and Islamic conflicts from the middle of the first millennium. Substantial libraries remained open in the capital and smaller ones in major cities until the Fourth Crusade (1204) and the capitulation to the Turks in 1453. Though libraries were significant in the early Eastern Empire, they had declined considerably by its end. In contrast, in the early medieval period (600–800) libraries in western Europe suffered from the fragmentation of the Roman Empire that brought chaos and instability.

In the West, monastic libraries, stimulated generally by the growth of the Benedictine order and the missionary activity of Irish and Anglo-Saxon monks, began to flourish widely, so that by the time of Charlemagne (c. 742–814) the preservation of remaining classical manuscripts and current writing was assured. Most of these libraries contained fewer than several hundred volumes. Cathedral libraries, which supported schools and scriptoria, grew slowly and began to serve clergy and civil servants not associated with a cloister. Some of these schools, such as the one in Paris, were antecedents of universities that appeared in the twelfth century; others, such as Chartres and York, were not. Later, other orders joined in copying activities.

The coming of the first Western European universities resulted in the formation of libraries with broader responsibilities than those of monasteries and archival repositories. Beginning with the early models of Padua, Salerno, Bologna, Paris, Oxford, and Cambridge, universities proliferated in Europe until, by the sixteenth century, they had become symbols of regional pride. Most of these institutions had central libraries, often built up by donations and under the custody of one of the masters. (The Bodleian Library at Oxford and the library of Trinity College,

Dublin, date from the early seventeenth century.) At Oxford, Cambridge, and elsewhere, individual colleges maintained separate and independent collections that only later, if ever, were integrated into the general collection.

Until the coming of moveable-type printing in the fifteenth century, books and archives were not always easily distinguished and may have been housed together. Within fifty years of the appearance of the moveable-type printing that Johannes Gutenberg developed about 1450, the presses of Europe increased production from a trickle to a flood of new scholarship and creative works, as well as of more accessible editions of the classic works from the ancient and medieval periods. These publications, possibly 100,000 titles by 1550, were both scholarly and popular works and contributed to creating and preserving the new ideas introduced by the Renaissance. While elite collectors would prefer manuscripts and lavishly illustrated volumes for some time to come, the less expensive and more portable printed books found an enthusiastic market—for example, in libraries and with collectors who would ultimately be benefactors of libraries.

Early Modern Libraries

This new category of book collectors who established personal libraries included members of the noble and upper classes, both those with hereditary titles and those who had accumulated wealth through commerce, manufacturing, and banking. They typified the enthusiastic response of the human spirit to the new ideas and knowledge that encouraged the building of libraries. Libraries became the possession not only of the privileged segments of society, but also, eventually, of the middle classes.

Early examples of this kind of princely library include that of Matthias Corvinus, king of Hungary (1440–1490), whose magnificent collection was dispersed by the invading Turks in the early sixteenth century. The Medici family in Florence exemplifies the merchant class; among the Medici projects was its great library, now the Laurentian Library, one of the

Missions often include libraries for the benefit of the indigenous people they serve. This photo shows the impressive library building in the Serampore mission compound in India. Photo by Klaus Klostermaier.

first modern libraries to have its own building (1571). Other wealthy families competed in building library and art collections that brought them esteem. The Papal library at the Vatican, which dates its modern founding to Nicholas V and Sixtus IV in the fifteenth and sixteenth centuries, is another good example. As books became more appealing as collectors' items, the gentleman's library became a trademark of the social class. Some of these collections grew into their own institutions; others merged through sale or bequest into other collections.

In the sixteenth century, libraries were increasingly attainable by the middle class through the proliferation of popular printed reading material. Books became cheaper and more widely available, and thus were collected by more people—a trend that has accelerated to the present. Political, religious, and social groups all tried to exploit the potential for promoting their messages; the Reformation and the civil conflicts accompanying it unleashed the power of political pamphlets and books. The Lutheran Reformers promoted education and reading as a public

good that demanded public support, which made libraries even more significant. The Jesuits likewise considered a serious education, requiring books and libraries, to be essential in promoting the Catholic faith. Beginning in the early eighteenth century the Society for Propagating Christian Knowledge (SPCK) and the Society for the Propagation of the Gospel in Foreign Parts (SPG) published and distributed Protestant religious and educational materials throughout the British Empire, and through the influence of the Reverend Thomas Bray (1656–1730) they established several kinds of libraries for popular and clergy use, notably in England and the British colonies in America.

The growth of nationalism and colonialism from the sixteenth through the nineteenth centuries supported the spread of books and libraries. The voyages of the Portuguese, Spanish, French, and British explorers yielded journals, maps, and specimens that resulted in further research and study and new books to record new ideas. Royal and national libraries, as well as libraries of societies and other institutions,

collected this material, which enriched their museums and laboratories as well as their libraries. The colonialism that often followed nationalistic adventuring provided opportunities for those with an interest in books and libraries to press for translation work, literacy, education, and cultural integration. In Asia and Latin America and then later in Africa, agencies in the colonizing nation established schools and libraries as desirable institutions in their nation's colonies abroad. Like the SPG, the Jesuit missionaries provided books and libraries for the colleges they established in China, Japan, India, Mexico, Peru, and elsewhere.

As they profited from their new ventures, royal houses and noble families began to assemble library collections that served as treasure houses of books. Beyond the local nobility and regional princes, the sovereigns of the royal houses began to consolidate their bibliographical holdings so that libraries were not dispersed periodically. Thus began the royal and ducal libraries in Europe that frequently merged into royal libraries for the nation and, ultimately, national libraries. These institutions, such as those in France, Prussia, Austria, Spain, and Sweden, were destined to become some of the great national libraries of the eighteenth century and beyond. They would be joined by comparable institutions such as the British Museum-Library (now British Library) in 1753, the U.S. Library of Congress in 1800, and the Russian State Library and the National Library of China in the twentieth century. These libraries, like those of other nations, continue to hold a place of honor and responsibility as repositories of the national cultural record. They perform a functional as well as a symbolic role because they frequently lead in organizing library activities for the nations they represent.

Libraries Since the Enlightenment

The history of libraries since the Enlightenment includes not only the proliferation of national, private, and university libraries, but also the extension of access to libraries by the broader citizenry, through public and school libraries. Professionalization—first

among academic librarians in Europe and then among public librarians in North America—became increasingly important. Among the issues that concerned the profession of librarianship were diversification of clientele, specialization in resources, and management of technological change.

University and college libraries continued to multiply in Europe and North America during the Enlightenment and the nineteenth century, the growth peaking only in the late twentieth century when fewer completely new academic institutions were created. As democratic movements in education propelled more students toward higher education, the libraries of collegiate institutions had to keep pace with new subject matter, new curriculum emphases, new teaching methods, new technologies, and fresh challenges in general. The mechanization of printing in the mid-nineteenth century further increased the production of books and journals of all kinds. Beginning in Germany and spreading to the North Atlantic community and beyond, the growth of graduate and professional programs leading to advanced degrees stimulated more comprehensive collections of research materials, which in turn stimulated the increased publication of books, reports, and journals. The great American university research libraries, such as those at Harvard, Yale, Columbia, and their public counterparts at Michigan, Illinois, California at Berkeley, and elsewhere, made their advances at the turn of the nineteenth and twentieth centuries and they have continued to grow to the present. The rise of capitalism in the nineteenth century extended the possibilities for accumulating wealth. Some entrepreneurs built and supported private libraries and art collections, many of which eventually became units of the great research libraries. Some, mostly in the United States, have retained their independent status, such as the Pierpont Morgan Library in New York, the Folger Shakespeare Library in Washington, D.C., and the Huntington Library in San Marino, California. These unique research libraries are monuments to the efforts and resources of individuals.

Along with existing national libraries, private libraries, and university libraries, social libraries made

an appearance in the eighteenth century. Most common in Northern Europe and North America, they focused on a carefully selected collection that served the purposeful leisure reading of a homogeneous body of readers. Frequently these libraries required membership and dues and were open only to those who met certain qualifications. An example of this was the Library Company of Philadelphia (1731), which issued shares to a limited number of persons, who thereby underwrote the support of the collection that was available to all members. Building on a few earlier models and a long informal tradition of popular literature, these libraries were sometimes sponsored by benefactors, societies, or associations. Peaking in number and popularity in the middle of the nineteenth century, they served as a kind of transition between libraries for the elites and the public library movement that followed. Variations in names and missions are reflected in the different forms that they assumed, such as athenaeums, lyceums, literary societies, and mercantile libraries, to name a few of the more common types. They differed from circulating libraries, which were primarily commercial lending operations for profit.

Though there are isolated early examples of public funds committed to community libraries, public libraries—that is, tax-supported libraries serving the general public—made their appearance in the mid-nineteenth century, initially in Great Britain and the United States. The growth of educational opportunities, the expansion of popular reading material, the pressure for democratic institutions, pride in local cultural institutions, and philanthropy—all played a part in bringing this movement together at mid century. In Great Britain the Public Libraries Act of 1850 permitted local municipalities to gain the approval of tax ratepayers to support a library (library provision became compulsory in 1964); major public libraries were created in Birmingham, Liverpool, and Manchester. In the United States, on a state-by-state basis, beginning with New Hampshire and other New England states from 1849 to 1854, taxing authority to permit the establishment of public libraries was approved. The Boston Public Library, which opened in

1854 under this legislation, became a model of what was possible, and in the next century the idea spread from New England to the whole United States. The large city public libraries, such as those in Boston, New York, Cleveland, and Detroit, joined the older idea of the municipal reference library, common in Northern Europe, with the popular reading room of the social library.

With the establishment of the American Library Association in 1876 and its British counterpart a year later, the new public libraries began to organize on a national and state basis to ensure that appropriate legislation was passed to support them through local taxation, and state and national support. The idea spread throughout Europe and to the nations touched by European culture. In most countries public libraries became an agency of the national, provincial, or state government, whereas in the United States they are locally authorized and maintained, even if they enjoy some state or federal support and are often under the general supervision of a state library commission or a state library. The modern library movement in North America and Western Europe, embracing various types of libraries, turned its attention to the education of librarians and to the issues that librarians faced in managing their enlarging collections, such as cataloging and classification and other matters relating to processing of materials, as well as to service to the public through the provision of reference works and other information services. Melvil Dewey (1851–1931) was an influential American librarian in this formative process.

Public libraries have frequently operated in conjunction with the public school system and may rightfully claim that they are institutions of continuing education for the citizenry. Because a public library serves the community interest with public funds, its role has been debated for the past two centuries. Some have seen its collections and services as a force for social advancement and cultural improvement, whereas others have seen public libraries as enforcers of the conformity that tends to restrict resources to those who represent the mainstream culture.

School libraries, while relative latecomers as a distinct entity, have their roots in small schoolroom collections. They found their earliest expression in secondary (or high) schools that became more common in the late nineteenth century in North America and Europe.

Cooperation between children's services in public libraries and school libraries has received much discussion, with some arguing that school libraries should focus on curriculum-related material and public libraries on general and leisure reading. Emphasis on the values of reading and the intellectual stimulation that it brings has benefited both approaches to children and youth. Standards for school libraries (or the lack thereof) adopted by governmental bodies have determined the course of school libraries, so that in some regions they are taken more seriously than in others.

Finally, there are "special" collections, which include governmental, business, association, museum, and subject-specific libraries. Though there are ancient examples of these kinds of collections, frequently integrated with archival repositories, they have proliferated since the beginning of the twentieth century. (The National Library of Medicine in Washington, D.C., is an example.) These libraries increasingly network with one another, using the latest information formats and technology. In the United States, networks are supported by the Special Libraries Association, founded in 1909, and similar bodies exist in other industrialized countries.

The Globalization of Libraries

Beginning in the mid-nineteenth century, efforts to unify the library profession began in the United States and Great Britain and then spread to Scandinavia and the rest of Europe and to societies under their cultural influence. National library associations came into being—some representing all types of libraries and others focusing on special types. During this period (1875–1925) world's fairs and convocations on both sides of the Atlantic provided opportunities for librarians from various countries to gather to discuss common practices, problems, and challenges, including

cooperation and the use of newer technologies. The beginning of what would be the International Federation of Library Associations (IFLA) in 1927, following an international conference in Rome, brought library leaders together and led to the promise of cooperation in matters of mutual interest, such as cataloging standards, interlibrary borrowing and lending, access to materials, disaster relief, and the stimulation of library development.

As the tensions of World War II, the Cold War, the independence struggles of the 1960s, and the post-Soviet period overshadowed national and local issues, international linkages and networking proved significant in preserving communication among librarians throughout the world. Cooperation with UNESCO, the major national libraries of the world, and the leading library associations enabled IFLA to become an effective forum for global librarianship. Today nearly every nation is represented in the several thousands of associations and institutions whose members attend annual conferences that convene around the world. The principal national libraries along with other major research libraries contribute significant resources and leadership to international cooperation initiatives.

Beginning about the time of World War II the new discipline of information science became important for libraries and librarianship. This field sought to study the properties of information—its creation, organization, use, preservation, and effects. In the last decades of the twentieth century, information technology—including digital catalogs, digital libraries, and the World Wide Web—became commonplace in the libraries of the industrialized world.

Thus, as the twentieth-first century begins, librarians everywhere are bound more closely than ever through their associations and electronic technologies and are better able to provide universal service to their patrons. The role of libraries as depositories of physical materials has broadened to connect users with a variety of information formats. Although libraries span the spectrum from the largest national institutions to the smallest village collections—from specialized research materials to the most popular items to read, view, or

hear—for millions of patrons around the world, they still serve as intermediaries between the creators and the consumers of ideas and information.

Abraham Lincoln, a lawyer and politician noted early on for his integrity and graceful rhetoric, was president of the United States during the U.S. Civil War; he is credited with saving the Union and freeing the slaves. After his assassination in 1865 his role was mythologized and remains controversial for those who see his Emancipation Proclamation as a failure and criticize his active support for resettlement of slaves in Africa.

Abraham Lincoln, as U.S. president during the American Civil War, is renowned for his role in freeing the slaves and saving the Union. He was born 12 February 1809, in a log cabin in Kentucky. His family moved several times, eventually settling in Illinois. Lincoln had little formal schooling; he was taught to read by his stepmother. He loved books, read for the bar, and eventually became a successful lawyer, well known for personal integrity. He married Mary Todd, the daughter of a slave-owner in Kentucky.

By 1832 Lincoln developed an interest in politics and served in the state legislature and in the United States Congress. He allied himself with the Whig Party, which distrusted what it perceived as a growing slave power in the South that corrupted the cause of democracy. Lincoln joined the Republican Party shortly after its founding in 1854. His reputation both as a lawyer and for his

personal integrity made him an obvious choice to challenge the incumbent Democratic senator from Illinois, Stephen A. Douglas. Their campaign centered on a series of debates over the extension of slavery into the territories that caught the attention of the entire nation. Newspapers printed the speeches verbatim. In the end the Democrat-dominated Illinois senate reelected Douglas, senators being elected by the state legislature rather than by popular vote at the time.

The losing senatorial campaign propelled Lincoln to the Republican nomination for president in 1860. Lincoln won the election, though with only a plurality of popular votes, from the northern tier of states. Many considered the Republicans too radical; most in the party, like Lincoln, were not abolitionists, but were opposed to the spread of slavery. Yet for many in

the South, Lincoln was seen as especially dangerous, which prompted Southern states to begin to secede from the union in December 1860. In spite of calls for him to intervene, Lincoln remained silent, thinking that it would be imprudent to act before his inauguration the following March. By then, however, eleven states

Calvin Johnson's ambrotype portrait of Abraham Lincoln in Pittsfield, Illinois, was taken on 1 October 1858, two weeks before the final Lincoln-Douglas debate in Lincoln's unsuccessful bid for the Senate. National Archives.

I am a firm believer in the people. If given the truth, they can be depended upon to meet any national crises. The great point is to bring them the real facts.

• Abraham Lincoln (1809–1865)

This Currier and Ives lithograph of Abraham Lincoln and his family was produced two years after the president's assassination as part of Lincoln memorabilia. National Archives.

had seceded and adopted a new constitution creating a Confederacy.

On 12 April 1861, the Civil War began when troops of the newly formed Confederacy fired on Federal troops attempting to resupply Fort Sumter, in Charleston harbor. Scholars disagree over responsibility for that event: Lincoln for ordering the fort resupplied, or the South for firing.

Early in the war, which both sides thought would be short, Lincoln had widespread popular support. He had early difficulties finding a general who could win. Frustrated by generals who lacked offensive drive and tactical knowledge, Lincoln resorted to reading everything he could about military tactics. Eventually, he settled on Ulysses S. Grant.

As the war dragged on, he faced increasing criticism domestically and even within his own cabinet. He responded by suspending the writ of habeas corpus, arresting and jailing those deemed a threat, and closing Democratic newspapers that criticized the war effort. Lincoln's justification for those actions was that they were necessary to preserve the Union.

Internationally, European nations seemed poised to intervene on the side of the South. Partially in

response, and following a Northern victory at Antietam, Lincoln issued the Emancipation Proclamation, which declared that slaves would be freed in states still in rebellion on 1 January 1863. Critics noted that no one was actually freed. But the proclamation gave new purpose to the war, deterred foreign intervention, and gave hope to those in slavery.

As the war continued, Lincoln's supporters feared that he could not be reelected. The Democrats nominated General George McClellan, whom Lincoln had dismissed. The fall of Atlanta in September 1864 restored confidence to the nation and brought a second term for Lincoln. With that election success, Lincoln pressed for the Thirteenth Amendment to the Constitution, which would actually free the slaves. Lincoln also turned toward the issues of Reconstruction. His proposed leniency toward the South faced substantial opposition in Congress. His pocket veto of the Wade-Davis bill in 1864 was a harbinger of difficulties to come.

At the end of the war, in April 1865, Lincoln visited the former capital of the Confederacy, Richmond, Virginia. There, witnessing his emerging iconic status, newly freed slaves pressed to touch his hand. Only days later, however, John Wilkes Booth assassinated

Lincoln addresses the crowd at the dedication of the Gettysburg National Cemetery, 19 November 1863. Sherwood Lithograph Co., circa 1905. National Archives.

Lincoln in Ford's Theater in Washington, D.C. In the national mourning that followed, those who only shortly before had been vehement political opponents turned their rhetoric to encomium.

The mythology that developed after Lincoln's assassination makes it difficult to separate fact from fiction. "Honest Abe" and "Father Abraham" are familiar sobriquets. "Great Emancipator," however, is controversial. Revisionists remind that the Emancipation Proclamation freed no one. Others accuse Lincoln of racism, pointing to his active support for resettlement in Africa. Lincoln's elegant rhetoric and political acumen did, however, hold the nation together. The hope of freedom his words engendered eventually became reality.

The mythology of Lincoln as the "Great Emancipator" reverberates throughout the world and continues to define Lincoln. This is particularly evident in Africa and Latin America. Russian texts point not only to Lincoln's antislavery stance, but also to Lincoln's heritage as a revolutionary figure. Like many

mythological figures, Lincoln rises above the reality and is interpreted by what people feel is important in their own world view.

Locke, John

(1632–1704)

ENGLISH PHILOSOPHER

John Locke was a leading intellectual in late seventeenth-century England whose work in philosophy, political theory, education, and theology played a major role in shaping eighteenth-century thought.

Born in Somerset, England, John Locke was educated at Westminster School and Christ Church, Oxford, where he earned his BA degree in 1656. Although educated in a traditional arts curriculum, he became interested in medicine and science and received a medical degree from Oxford in 1675. His association with people such as the physician Thomas Sydenham and the physicist Robert Boyle brought him into contact with some of the leading scientific ideas of the day. Locke became a fellow of the newly founded Royal Society in 1668. His subsequent work in other disciplines, such as philosophy, political theory, education, and theology, would make tremendous contributions to eighteenth-century thought.

Locke was active in public affairs through his involvement with Lord Ashley, later the first earl of Shaftesbury, who was one of the most powerful leaders of the day. Locke's political fortunes waxed and waned with Ashley's from 1667 to 1683. Serving as secretary to the newly established Board of Trade and Plantations from 1673 to 1675, Locke was involved in a variety of policy debates on commercial affairs. He lived abroad for health reasons from late 1675 to spring 1679, returning to the Shaftesbury household during the Exclusion Crisis, when Protestant nobles led by Shaftesbury sought to exclude James, the Catholic brother of King Charles II, from succeeding

to the throne. After Shaftesbury's fall from power in 1681, Locke remained in England until the Rye House Plot (to assassinate King Charles II and his brother James) was discovered, and he fled to Holland in 1683. Locke lived in exile in Holland until William and Mary assumed the throne in 1688.

Returning to England when William and Mary assumed the throne, Locke published books in a wide range of fields that had occupied him during the 1680s. *A Letter Concerning Toleration* and *Two Treatises of Government* were published anonymously in 1689. These were followed by four editions of *An Essay Concerning Human Understanding* (1690, 1694, 1695, 1700), two additional letters on toleration (1690, 1692), selected papers on interest and money (1692, 1695), *Some Thoughts Concerning Education* (1693), *The Reasonableness of Christianity* (1695), and two *Vindications of the Reasonableness* (1695, 1697).

From 1696 to 1700 he was a commissioner on the Board of Trade and Plantations. Retiring for health reasons, Locke spent his last few years revising the *Essay* and writing commentaries on the letters of Saint Paul. Along with the philosophical essay, "The Conduct of the Understanding," these theological writings were published posthumously.

An Essay Concerning Human Understanding is one of the seminal contributions to British empiricism (a theory that all knowledge originates in experience). His primary goal was to grasp the limits of human understanding. He criticized the notion that people possess innate ideas about the world. People acquire knowledge about the world through simple and complex ideas that originate in sensation and reflection.

Every man has a property in his own person. This nobody has a right to, but himself. • John Locke (1632–1704)

John Locke's interdisciplinary work in political theory, education, and theology made tremendous contributions to eighteenth-century thought.

Locke also explored the role of language in human knowledge and tried to mark out the relationship between reason and faith. Locke's theory of ideas and his analysis of substance, primary and secondary qualities, personal identity, and the problem of free will set the terms of debate for the philosophical work of Francis Hutcheson, George Berkeley, and David Hume.

Although written initially during the Exclusion Crisis of the early 1680s, Locke's *Two Treatises* was published as a defense of the ascension of William and Mary to the English throne. Rejecting the English political writer Robert Filmer's theory of the divine right of kings, Locke argued that political power flows directly from the people. In the hypothetical state of nature regulated by God's natural law, people are free and equal beings possessing certain inalienable rights. In order to protect their lives, liberties, and properties people join into political communities.

Political power thus arises to accomplish limited goals. If political leaders extend their power too far, the people reserve the right to revolt against them. Locke's social contract theory became the hallmark of Whig ideology in Britain throughout the eighteenth century and played a major role in the founding of the United States.

Like his philosophical and political ideas, Locke's educational and theological writings were grounded in a respect for the individual and the power of reason to order human affairs. He was sensitive to the role that experience plays in the education of youth and the development of one's moral character. He viewed a church as a voluntary association of people who come to worship together in matters of faith. He argued for toleration among Protestant sects who were potentially willing to tolerate the religious opinions of the other sects. His goal was to convince Protestant groups that they had an interest in tolerating one another. Significantly, this toleration did not extend to Roman Catholics, who, Locke believed, were committed to the secular authority of the pope. Much of the British, French, and U.S. versions of the Enlightenment (a philosophic movement of the eighteenth century marked by a rejection of traditional social, religious, and political ideas and an emphasis on rationalism) can be seen as working out many of the ideas initially developed by Locke.

Long Cycles

Only since the nineteenth century did the idea of “progress” begin to persuade many people that they lived in a world of unidirectional development. Throughout history long cycles—whether biological, sociocultural, political, or economic—have followed an up-down-up pattern generated by factors occurring within it. The concept of cycles is itself cyclical, going out of fashion when things appear to be on the upswing.

Sociocultural and political long cycles have received much attention throughout history. The Chinese—at least until the rise of Marxist historiography in China—and the ancient Egyptians conceptualized their history in terms of dynastic cycles, as did foreign students of China and ancient Egypt. Two fourteenth-century examples illustrate that point. China’s Luo Guangzhong, in the novel *San guo zhi yan yi* (Romance of the Three Kingdoms) wrote: “the empire, long divided, must unite, long united, must divide.” In Morocco, the historian Ibn Khaldun (1332–1406) identified generational cycles in dynasties in which the achievements of the founders were buried by the third generation, thus giving rise to a new dynasty. Reference to such generational cycles appear in Ancient Greek tragedy, which was marked by the principal character’s taking a tragic course of action as a result of the actions of those in previous generations, and in alternating progressive and conservative U.S. political thought and policy, as identified by the historians Arthur M. Schlesinger and Arthur M. Schlesinger Jr.

But the concept of long cycles raises the question, how long is long? When, for example, does one generation end and another begin, since people are born all

the time? In the case of climatic cycles, the sociologist Sing Chew identifies cycles that extend for millennia and that had important social consequences, such as ages during which civilization all but disappears. Climatologists can distinguish much longer cycles still, with biological and hence social consequences. So how long is long? Aristotle observed that people have a hard time identifying the long cycles they live through because a cycle—or even one of its up or down phases—can last more than a lifetime. We can also identify shorter cycles nested within longer and these within even long ones.

Cycles versus Progress

Only since the nineteenth century did the idea of “progress” begin to persuade many people that they lived in a world of unidirectional development; it was at that point that the concept of cycles began to lose fashion. Cycles were replaced by stages or a staircase of steps leading ever upward from “traditional” society ultimately into paradise. That was the view of the philosopher G. W. F. Hegel (1770–1831), who developed the idea of a dialectic of thesis, antithesis, and (improved) synthesis; it was also the view of the political theorist Karl Marx (1818–1883), who used Hegel’s dialectic to explain how political systems developed and were replaced. Subsequent Euro-American historians, philosophers, and social scientists have followed in their path, down to the scholar Francis Fukuyama, who pronounced the end of history in 1992.

But as most of the world was left out of (or fell or was pushed backward and downward by) the Eurocentric view of stages of historical development,

cycles have come back into fashion again. That happens when things are going badly: when times are bad, people hope that they are only in a temporary downward phase of a cycle that will turn up again. When things are going well, on the other hand, they hope that good fortune will last forever, and cycles again go out of fashion. So interest in cycles is itself cyclical. Since 1967, the world economy has been in a long cyclical downswing of which (as on previous occasions) some—recently especially East Asia—have been able to take advantage to improve their position in the world economy at the expense of those most hit by the crisis of a long economic cycle, and interest in long economic cycles has mushroomed. Some, such as the economist and sociologist Joseph Schumpeter (1883–1950), believe that cycles are real and inextricable features of political life. Throughout world history, long cycles have created opportunities for social and political action on the upswing, and they have set limitations to such action on the downswing.

Relating Economic Long Cycles to Other Cycles

The Dutch economists J. van Gelderen (1891–1940) and Samuel de Wolff (1878–1960) and then the Russians Leon Trotsky (1879–1940) and Nikolai Kondratieff (1892–c. 1938) identified the phenomenon of the long economic cycle in the early years of the twentieth century. Long cycles are sometimes termed “Kondratieff’s waves” after the latter, who saw cycles of fifty to sixty years in length, about half of them expansive and the rest contractive. Strictly speaking, Kondratieff saw long swings only in prices, and mostly in the economies of single countries. Those cycles are complemented by twenty-year-long cycles, originally identified in the construction industry by and named after the economist Simon Kuznets (1901–1985). Beginning with Schumpeter in the 1930s, technological invention and (more importantly) its implementation through economic innovation have been seen as the engine that drives the cycles. Additionally, the search for both kinds of long cycles has been extended from

prices to production and income, as well as to an ever-wider world political economy.

During the present downturn—which began after the post–World War II boom came to an end—Kondratieff long cycles have been traced even farther back, to the 1700s by the economist and historian Andre Gunder Frank, and then to 930 CE starting in China by the political scientists George Modelski and William Thompson. The social scientist Joshua Goldstein related major war to long economic cycles. The sociologist Albert Bergesen related long economic cycles to cycles of colonialism; with Immanuel Wallerstein he related them also to the rise and decline of hegemonic power in the world. The sociologist Beverly Silver related long cycles to labor movement. Marta Fuentes, writing with Andre Gunder Frank, related them to other social movements, and students in a seminar at the University of Amsterdam related them to social phenomena as diverse as colonialism and philosophy. Bergesen also attributes changes in artistic style and the current fashion for postmodernism to long hegemonic and economic cycles. Modelski and Thompson however, find two Kondratieff economic cycles for each long hegemonic cycle. Yet all long cyclists still remain in a small—though growing—minority. Some economists, especially Solomos Solomou, dispute on empirical grounds the possibility of measuring such long cycles, and indeed, their very existence. Peter Grimes devoted ten years to searching for and devising ingenious measures and indices to identify worldwide Kondratieff cycles, or even waves, but was unable to find them empirically.

Very Long Cycles

Several scholars have identified even longer political economic social cycles, some with two-hundred- or three-hundred-year up and down phases, or even longer. Moreover, these long cycles are now being traced, identified, and dated back into the fourth millennium BCE with near simultaneous periods of expansion across most of Afro-Eurasia, which suggests that already then the peoples of this land-mass were part of a single world system. Expansions

were followed by subsequent long periods of crisis, such as the “dark age” between 1200 and 1000 BCE, when civilization largely died out in Anatolia, Central Asia, and North Africa, and when Moses led his people out of crisis-weakened Egypt. These were periods as well of breakdown of empires, near-continuous wars among smaller political units, and heightened authoritarianism within them. The question is whether or not the study of these earlier cycles will help us understand and act in our present and future.

Martin Luther, the sixteenth-century leader of the Protestant Reformation, was a German monk who began to preach against the Catholic Church's doctrines and practices, especially the legitimacy of indulgences, the Mass as a representation of Christ's sacrifice, and vows of celibacy required for priests. Martin Luther initiated a movement of criticism that extended beyond the scope of his own reform efforts, especially during the Enlightenment.

Martin Luther was a German monk, teacher, and preacher whose work helped to usher in the Protestant Reformation. Luther was born in the German town of Eisleben, Saxony. He attended Erfurt University from 1501 to 1505, after which his father expected him to pursue the study of law. But Luther was strongly attracted to the order of the Augustinian Hermits in Erfurt, which he joined on 2 July 1505, in direct disobedience to his father's wishes. Luther was ordained to the priesthood in 1507 and celebrated Mass, considered to be a representation of the sacrifice of Christ. Luther moved to the Augustinian house in Wittenberg in 1510, under the authority of his superior, Johannes von Staupitz. Luther became a doctor of theology in 1512, and began to lecture on scripture.

Beginning in 1515, Luther began to experience terrors in his conscience on account of his awareness of his sinful affections, which led him to feel that he was under the wrath of God. Luther termed these experiences *Anfechtung* (trial or assault), following the language of German mystics such as Johannes Tauler. Luther at first thought that his experience of trial was meant to free him from selfishness in

Martin Luther in 1546, the year of his death.

conformity to Christ, so that he might be condemned and crucified with Christ. Since Christians ought to be willing to be punished to hell for their sins, Luther objected to the preaching of indulgences, which were a way Christians could lessen the punishment they owed for sins by means of funds given to the church. In 1517, Luther sent his Ninety-five Theses debating the legitimacy of indulgences to other universities and bishops, which were published and widely distributed very quickly, making Luther internationally famous. The pope began hearings in Rome to excommunicate Luther on the basis of the way Luther questioned the authority of the pope in the Ninety-five Theses.

In light of his growing controversy with Rome, and his own terrors of conscience, Luther's teaching

continued to develop. Luther was especially moved by Staupitz's claim in confession that Christ in his death had made the sins that terrified Luther his own, and wanted instead to give Luther his righteousness, in an event of faith that Staupitz called "the royal marriage." Luther took this idea of Staupitz's and made it central to a new understanding of faith, which some date around the year 1519, although others date it as early as 1515. After 1519, Luther began to teach that nothing a person can do could free that person from the feeling of sin and wrath in the conscience. Only Christ can do this by his death on the cross, which he offers to sinners in the preaching of Gospel. Only faith in the Gospel and trust in the work of Christ can bring peace to the terrified conscience. The Mass does not represent

Wherever the battle rages, there the loyalty of the soldier is proved; and to be steady on all the battlefield besides is mere flight and disgrace if he flinches at that one point. • **Martin Luther (1483–1546)**

the sacrifice of Christ, but offers the promise of forgiveness. When people believe the Gospel, argued Luther, they are then spontaneously led to share the burdens of their neighbors out of love, but none of this frees them from sin or makes them righteous before God. Luther outlined this teaching in several treatises written in 1520.

By 1521, Luther's refusal to recant his teaching led him to be excommunicated by the pope and placed under a ban by the Holy Roman Emperor, Charles V. However, Luther's own ruler, Frederick the Wise, Elector of Saxony, did not think that Luther received a fair hearing, and so protected him from both the pope and the emperor. In the same year, Luther concluded that monastic vows contradicted genuine Christian faith, and by 1525 Luther married a former nun, Katherine von Bora. Luther sought to reform the churches in Saxony gradually, following the lead of the elector, which brought him into conflict with those who wanted to pursue reform more quickly. Luther also came into conflict with the philosopher Erasmus over the free choice of the will, and with the reformers in the Swiss territories over their understanding of the Lord's Supper, leading to a permanent break between the Lutheran and Reformed churches. Luther continued to lecture on scripture in Wittenberg until his death in 1546, in the hope that he could teach the next generation the true meaning of the Gospel.

By rejecting monastic vows as a legitimate expression of Christian faith, Luther raised marriage and the family to genuinely spiritual estates, and made them the locus of education in faith by means of his

German translation of the Bible and his Small Catechism. By allowing the Elector of Saxony to protect him after 1521, Luther began a period in which temporal rulers would be given the power in the church previously accorded to bishops, which would raise problems of its own over time. By testing the whole of received tradition by the sole criterion of the clear word of God in scripture, Martin Luther initiated a movement of criticism that extended beyond the scope of his own reform efforts. The Reformed and Anabaptist movements used the same criterion to criticize both the Roman Church and Luther himself. The criticism of both scripture and tradition by reason in the age of the Enlightenment can be seen as a further development of the comprehensive critique of tradition initiated by Luther.

Berkshire's authors and editors welcome questions, comments, and corrections:
worldhistory.updates@berkshirepublishing.com

The emergence of Macedon as a major imperial power during the fourth century BCE was a pivotal event in world history, changing the focus of culture and politics to those of the Greeks it conquered. The demise of the Macedonian kingdoms did not, however, mean the end of Greek influence in their former territories. Macedonian conquest had effectively linked culturally and commercially the entire vast territory from India to the Mediterranean.

During the fourth century BCE, in the span of little more than fifty years, the ancient center of gravity in southwest Asia shifted from Mesopotamia (between the Tigris and Euphrates rivers) and southwestern Iran to the eastern Mediterranean basin. The Persian Empire, which had dominated the vast region from India to Anatolia (in modern Turkey) for more than two centuries, disappeared, being replaced by a series of Macedonian kingdoms. The social and cultural changes were equally profound. Greeks became the new elite, and knowledge of the Greek language and Greek culture became the key to social and political influence. The incentive to learn millennia-old hieroglyphic and cuneiform scripts and the cultures encoded in them declined sharply, leading to their eventual disappearance during the early centuries CE.

History

Balkan (relating to countries of the Balkan Peninsula, including Macedonia) nationalism has made the identity of the Macedonians a controversial subject. Recent discoveries suggest, however, that the

Macedonian language was, in fact, a form of Greek related to the dialects spoken in northern Greece. Although Macedonian may have been a Greek dialect, this linguistic relationship was obscured by sharp differences in culture between Macedonians and Greeks. The most important of these differences was that Macedon was a territorial state ruled by kings, not a state divided into mutually independent city-states, as Greece was.

During most of its early history the Macedonian monarchy was weak. Situated in the northern Balkans, Macedonian kings, to retain their thrones, had to struggle constantly against foreign enemies and powerful nobles with royal ambitions. Only in the mid-fourth century BCE did this situation change as a result of the political and military reforms of King Philip II (360–336 BCE), which transformed Macedon into the strongest military power in the eastern Mediterranean and overseer of an empire that stretched from southern Greece to the Danube River. Threatened with ruin by Philip's assassination in 336 BCE, his work was saved by the accession of his son Alexander III (Alexander of Macedon, commonly called Alexander the Great, 336–323 BCE), who carried out his father's plans to invade the Persian Empire.

Alexander was twenty years old when he became king. When he died in Babylon in 323 BCE at the age of thirty-three, he had transformed the world that the Greeks knew. In the course of a campaign that extended from the Mediterranean to western India, his army repeatedly defeated the armies of the Persian Empire and brought under Macedonian rule Egypt and all of ancient southwest Asia. Whatever plans Alexander may have had for his empire, however, were aborted by his premature death, leaving to his

I am not afraid of an army of lions led by a sheep; I am afraid of an army of sheep led by a lion. • **Alexander the Great (356–323 BCE)**

successors the task of creating a new state system in the territories of the former Persian Empire.

Four decades of bitter struggle were required for that state system to emerge. Efforts to keep Alexander's empire intact were frustrated by the ambitions of his generals, who sought to divide it among themselves. When the wars of Alexander's successors ended in 281 BCE, his empire had been replaced by a state system dominated by three large kingdoms: that of the Antigonids in Macedon, the Seleucids in Asia, and the Ptolemies in Egypt. From the beginning, however, the new kingdoms' survival was repeatedly threatened by both internal and external threats.

The Seleucids' kingdom was the most vulnerable. King Seleucus I (311–281 BCE) ceded India to Chandra Gupta (c. 324–300 BCE), the founder of the Maurya dynasty, and his successors lost much of the territory conquered by Alexander in Central Asia to the Parthians (Iranian-speaking nomads) and rebellious Greek settlers, who carved out kingdoms in eastern Iran and Bactria (modern Afghanistan). Meanwhile, struggles with the Seleucids to preserve their holdings in southern Syria and Palestine and native rebellions in southern Egypt undermined the Ptolemies' hold on Egypt. Attempts to restore royal authority in the early second century BCE by King Antiochus III (223–187 BCE) and King Ptolemy V (204–180 BCE) were frustrated by Rome, and a little more than a century later the last vestiges of Alexander's conquests had disappeared, having been absorbed into the empires of the new masters of southwest Asia: the Romans and the Parthians.

This *niketerion* (victory medallion) bearing the profile of King Philip II of Macedon (d. 336 BCE), was probably minted during the reign of the last Roman emperor, Alexander Severus.

Macedonian Kingdoms

The emergence of the Macedonian kingdoms created a new world for the Greeks. While the cities of Greece declined, the kings founded splendid new Greek cities in their kingdoms. Although Greek literature contains little evidence concerning the operation of the Macedonian kingdoms, archaeological evidence in the form of inscriptions and papyri has remedied this deficiency, making clear that the kingdoms were conquest states organized on the basis of two principles. First, a kingdom belonged to the king; and second, his business had priority over everything else. Although these principles were common to all the kingdoms, their application is clearest in Egypt because of the rich papyrological (relating to papyrus) evidence for the functioning of the government.

Egypt's wealth was its rich agricultural land, which the Ptolemies divided into two categories: royal land dedicated to basic agricultural production and "released land" used to support soldiers, government officials, and even Egypt's numerous temples. The main nonagricultural sectors of the economy, such as textile, papyrus, and oil production, were organized as state monopolies in order to maximize royal revenue. An extensive administration based in the capital Alexandria but with agents—Greek at the upper levels and Egyptian at the lower—throughout Egypt supervised the system. Over the system as a whole was the king, who ruled as an autocrat whose word was law. The establishment of a cult of the living ruler and his ancestors enhanced the legitimacy of royal autocracy and afforded subjects a means of demonstrating their patriotism, loyalty, and gratitude for the protection and other benefits provided them by their ruler.

Life and Culture

Whereas Alexander may have hoped to govern his empire with the aid of native elites who accepted his rule, his successors rejected that hope, relying instead on Greeks to fill key administrative posts. As a result, for more than a century Greeks moved east to populate the new cities founded by the kings. For the first time Greeks and other travelers could be confident that the Greek language was sufficient to find them ready welcome everywhere from the Mediterranean to the borders of India.

The greatest of the new cities was Alexandria in Egypt, which eventually grew to enormous size with a population reaching half a million people and possessed splendid public buildings and amenities unknown to the cities of old Greece. The greatest of these amenities was the lighthouse known as the “Pharos,” a 121-meter-high polygonal tower whose beacon fire guided ships to Alexandria harbor.

Alexandria was the first of Alexander’s foundations and the site of his tomb, but the Ptolemies made it the capital of Egypt and the premier city of the Hellenistic

(Greek) world. Built on the site of an Egyptian town named “Rhakotis,” Alexandria possessed a multiethnic population that included Macedonians, Greeks, Egyptians, and a large Jewish community. Despite the diversity of its population, Alexandria was organized as a Greek city-state, and only Greeks and Macedonians enjoyed full citizenship rights.

In the new kingdoms culture became a tool to enhance royal prestige. Like Alexander, the Ptolemies encouraged prominent Greek intellectuals to settle in Alexandria. Supported by Egypt’s riches, they subsidized artistic and scientific work by establishing cultural institutions of a new type, namely, the Museum, a research center where scholars supported by government stipends could pursue their studies, and the Library, which was intended to contain copies of every book written in Greek. Eventually, its collection supposedly reached 700,000 papyrus rolls.

The Ptolemies were passionate about expanding the royal library’s collections. Jewish tradition claimed that King Ptolemy II ordered the preparation of the Septuagint, the Greek translation of the Jewish Bible; King Ptolemy III stole the official Athenian copy of

the works of the great Greek tragedians Aeschylus, Sophocles, and Euripides. However its books were acquired, the Library offered unprecedented resources for scholarly research in every field of intellectual endeavor. Doctors and writers receiving government stipends had, however, to earn their keep, serving as physicians and tutors to members of the royal family and celebrating its achievements. The poet Callimachus created a monumental catalogue of 120 books in the library while writing elegant poems in honor of the royal family. Similarly, the poet Theocritus also extravagantly praised the achievements of Ptolemy II in his poems.

The greatest achievements of Hellenistic intellectuals, however, were in scholarship and applied science, where their works remained standard for the rest of antiquity. Callimachus and other scholars such as Zenodotus and Aristarchus founded the critical study of Greek language and literature and prepared standard texts of the Greek poet Homer and the other poets that are the ancestors of those texts we still use. The mathematician Euclid summed up the results of three centuries of Greek mathematics in his *Elements*, which was still used to teach plane geometry until the early twentieth century. The geographer Eratosthenes established the principles of scientific cartography and produced a strikingly accurate estimate of the circumference of the Earth on the basis of evidence collected by Hellenistic explorers. The physicist Ctesibius pioneered the study of ballistics and the use of compressed air as a source of power, while other scientists experimented with the use of steam to operate simple machines. Medicine also advanced greatly. The doctors Herophilus and Erasistratus made fundamental discoveries concerning the anatomy and functions of the human nervous, optical, reproductive, and digestive systems by dissecting corpses, even vivisectioning criminals whom the government provided for the advancement of science.

Alexandria was the greatest of the new cities founded by Alexander and his successors, but it was not atypical. The rulers of the other kingdoms pursued the same goals as the Ptolemies in their urban plans. Like Alexandria, the Seleucid capitals—Antioch

in Syria and Seleucia in Mesopotamia—were large-scale, planned, multiethnic urban centers with splendid monuments. Even in remote Bactria, archaeology has revealed at Ai Khanum near the Oxus River a Greek city with broad streets, a special government center, and elegant temples and villas. These cities were also cultural centers. Thus, Antioch also had a library like Alexandria, albeit smaller, as did the city of Pergamon in Anatolia, while at Ai Khanum the remains of imported Greek books have been found in the royal treasury. The kings also encouraged native elites to transform their cities into Greek cities complete with the same amenities found in the royal capitals by rewarding them with citizenship and tax privileges.

End of the Macedonian Era

Despite their achievements, the Macedonian kingdoms had serious weaknesses, most importantly the limited support of their non-Greek subjects. In these kingdoms ethnicity and privilege were linked, and Greek identity was the ethnicity that counted even though Greeks and Macedonians made up less than 10 percent of their population. Thus, although elite non-Greeks sought Greek status through education, few Greeks acquired a sound knowledge of the languages and cultures of Egypt and Asia. The new Greek cities were essentially islands of foreign domination and culture in a largely non-Greek landscape. As a result, native unrest and separatism prevented the last Ptolemies and Seleucids from mounting effective resistance to the advances of the Romans and Parthians.

The end of the era of the Macedonian kingdoms did not, however, mean the end of Greek influence in their former territories. Macedonian conquest had effectively linked culturally and commercially the entire vast territory from India to the Mediterranean, and that linkage not only survived but also expanded westward to the Atlantic and northeastward toward China under Roman and Parthian rule. Likewise, Greek culture and the Greek language also continued to function as a common elite culture and language in the

Roman West, while Greek art and the Greek alphabet found new uses in Central Asia, providing Buddhism with the iconography (traditional images or symbols associated with a subject, especially a religious or legendary subject) to express the humanity of the Buddha and enabling the Saka and other peoples of the region to write their languages for the first time.

Machiavelli, Niccolò

(1469–1527)

ITALIAN POLITICAL PHILOSOPHER

Niccolò Machiavelli has exerted an extraordinary influence on modern thought and practice throughout the world. His writings and career are subject to varied interpretations, but the most common have given rise to a word found in most languages, *Machiavellianism*, suggesting deceit, tyranny, and the dictum that the end justifies the means.

Born in Florence in 1469, Niccolò Machiavelli was one of four children of Bernardo Machiavelli, an impoverished lawyer whose ancestors had held important political positions until the rise of the de' Medici dynasty. Niccolò received a mediocre education, but his father's well-stocked library provided some compensation. Machiavelli's own writings would eventually find a prominent place in the Western canon, and thus on the shelves of libraries around the world—although his most important work, *The Prince*—a manual predicated on his thesis that humankind is essentially evil, and in which he thus advised rulers to be constantly vigilant—was banned by the Catholic Church soon after publication.

In early adulthood Machiavelli witnessed a momentous event that would help shape his character and career. In 1494 King Charles VIII of France invaded Italy to press a claim to the kingdom of Naples. The four dominant city-states—Florence, Venice, Milan, and the Papal States—were thrown into turmoil. In Florence the incompetent ruler, Piero de' Medici, was forced into exile, and a republic was established. On 19 June 1498 Machiavelli was elected to the important post of secretary of the second chancery, a

government organ dealing with both domestic and foreign affairs.

Machiavelli frequently undertook diplomatic missions, on which his primary responsibility was to observe and report back to Florence. He proved to be an astute observer. Among the major political figures whom he visited were King Louis XII of France; Maximilian I, Holy Roman emperor; Pope Julius II; and Cesare Borgia, the warrior son of Pope Alexander VI and the ruler of the papal state Romagna. None made a greater impression on him than Cesare Borgia.

In 1512 Spanish troops from the kingdom of Naples entered Tuscany and restored Florence to de' Medici rule. Machiavelli was summarily dismissed from the government and briefly imprisoned. Bereft of a job, he retired with his wife and children to the family villa Sant'Andrea, outside of Florence. Most of his life after 1513 was spent in writing, and his use of Italian for his writings helped to promote Italian as a major literary language.

Machiavelli's most important work was *The Prince*, a manual for rulers that he completed in December 1513. He began his manual with the assertion that he was writing a realistic guidebook, based on his own experience. Predicated on his thesis that humankind is essentially evil, he advised rulers to be constantly vigilant. They must be perceived as being just, compassionate, religious, and trustworthy, but even if they actually possessed such virtuous characteristics, they must be prepared to abandon them when it suited their own interests. A prince should wish to be feared rather than loved, if he has to choose between fear and love. He should not object to being considered a miser because too much generosity leads to higher

The first method for estimating the intelligence of a ruler is to look at the men he has around him. • Niccolò Machiavelli (1469–1527)

Santi di Tito, *Niccolò Machiavelli* (late 16th c.). Oil on canvas. This posthumous portrait hangs in the Palazzo Vecchio, Florence.

taxes and thus alienates the people. Machiavelli also urged rulers to take advantage of opportunities and not assume that chance, or “fortune,” is the major determinant of events. The ruler most worthy of emulation, according to Machiavelli, was Cesare Borgia because he knew how to combine law and order with deceit, political assassination, and secrecy. *The Prince* ended with a highly emotional appeal to Lorenzo de’ Medici, to whom the book was flatteringly dedicated, to form a national army and drive foreigners out of Italy. Because the ideas expressed in *The Prince* ran counter to Christian morality, the book was subsequently condemned and placed on the Index of Prohibited Books of the Catholic Church.

After *The Prince* Machiavelli resumed writing a book he had begun earlier, *The Discourses on the First Ten Books of Livy*. Contrary to his support of autocracy in *The Prince*, he now advocated the type of government that had existed under the Roman republic. He saw in this republic a balance between

the interests of the aristocracy and those of the common people. He praised Rome’s pagan religion as a necessary foundation for the state, unlike the Roman Catholicism of his own day, which he blamed for Italian corruption and weakness.

During this period of enforced retirement Machiavelli turned his facile pen to other literary forms, such as poetry, drama, and biography. His most successful genre was drama, and his *The Mandrake Root*, an amusing as well as anticlerical comedy, attracted wide audiences. *The Mandrake Root*, like his novella *Tale of Belagor, the Devil That Took a Wife*, also reflected contempt for women that verged on misogyny.

After Lorenzo de’ Medici’s death in 1519, Machiavelli’s relations with the de’ Medici family improved. He was commissioned by Cardinal Giulio de’ Medici and the University of Florence to produce a history of Florence. Beginning the narrative with the fall of Rome, he traced Florentine history to 1492. In describing the de’ Medici period he wrote more as a fawning politician than as a historian.

In 1525, as Machiavelli prepared to present his *Florentine Histories* to Pope Clement VII (the former Cardinal Giulio de’ Medici), the Italian peninsula was threatened by Charles V, Holy Roman emperor and king of Spain. Two years later Charles V’s Spanish infantry and German Lutheran troops sacked Rome, causing the de’ Medici Pope Clement VII to take refuge in Castel Sant’Angelo and the de’ Medici government in Florence to collapse.

A republic was quickly reestablished in Florence, but because Machiavelli had been associated with the de’ Medicis, he was excluded from office, much to his distress. He died on 21 June 1527 and was buried in the Church of Santa Croce. A contradictory figure in his own time, Machiavelli continues to elicit blame and praise in the twenty-first century, but his influence on political thought is undeniable.

Magellan, Ferdinand

(1480–1521)

PORTUGUESE EXPLORER

The circumnavigation of the globe in the early sixteenth century by the Portuguese explorer Ferdinand Magellan provided the first empirical proof that the Earth is round. Magellan is also renowned for discovering the strait at the southern tip of South America that now bears his name.

The Portuguese sailor Ferdinand Magellan led a crew whose survivors circumnavigated the Earth from 1519 to 1522. Most people in the sixteenth century understood that the Earth is a sphere; despite longstanding beliefs to the contrary, as early as the third century BCE the Greek mathematician and geographer Eratosthenes proved this fact by geometry. Nevertheless, Magellan's circumnavigation was the first empirical proof that the Earth is round. Magellan also proved that the Americas were not necessarily a barrier between Europe and Asia; rather, merchants could sail from one continent to the other by passing through a strait Magellan discovered at the southern tip of South America, duly named the Strait of Magellan.

Born about 1480 in either Sabrosa or Porto, Portugal, Ferdinand Magellan was the son of Rui de Magalhaes and Alda de Masquita, both nobles. Queen Leonor of Portugal brought Magellan as a boy to Lisbon, where he served as her page. He joined the Portuguese fleet in 1505 and sailed to the Indian Ocean, where he served until 1512. Wounded in one battle and decorated for valor in another, Magellan rose to the rank of captain in 1512 and returned briefly to Lisbon. The next year he was wounded again, in a battle against Muslim Arabs, or Moors, in the Mediterranean Sea. Despite Magellan's wounds and

heroism, King Manuel of Portugal refused twice to increase his pay, suspecting that Magellan had traded with the Moors. Magellan denied the charge, and in 1517 pledged loyalty to Spain, Portugal's rival.

The rivalry arose between Spain and Portugal over which nation would be the first to circumvent the land route from India to the Iberian peninsula over which merchants carried spices. The Genoese sailor Christopher Columbus thought he had done this in 1492 by sailing west from Spain, on whose behalf he set out. But by Columbus's death in 1506, Europe's monarchs and merchants understood that he had found not India but a new land altogether. In the meantime, Portugal had beat Spain in the maritime race to India when Portuguese sailor Vasco da Gama reached Calicut, India, in 1498, claiming the Indian Ocean and with it the spice trade.

The Spanish were thus stuck with a new continent they initially regarded as an impediment on the way to Asia rather than an economic opportunity of its own. Spanish explorer Vasco Nuñez de Balboa sparked a glimmer of hope by discovering a new ocean, which Magellan would later name the Pacific, in 1513. If a strait could be found between the Atlantic and Pacific oceans, Spain would be able to sail west to Asia and contest Portuguese control of the spice trade.

This task fell to Magellan. His status as a nobleman, his service in the Indian Ocean, and his heroism inspired the confidence of Emperor Charles V, the king of Spain, who in March 1518 granted Magellan five ships. After amassing provisions and a crew of nearly 270 men, Magellan sailed on 20 September 1519, southwest into the Atlantic Ocean in search of a strait through South America.

The Straits of Magellan at the southern end of South America.

He faced trouble from the outset. Each excursion into a river of South America ended in a cul de sac, and by March 1520, winter in the Southern Hemisphere prompted Magellan to halt at Port San Julian on the eastern coast of South America and put his crew on short rations. Furious that Magellan had not retreated north to warm waters, the captains of three of his ships mutinied. Magellan restored order, only to have one ship run aground. Worse, while in port Magellan discovered that his suppliers had cheated him with provisions for six months rather than the eighteen he had ordered. The men had no choice but to eat anything they could find: worms, insects, rats, or sawdust.

With only four ships and short of food, Magellan renewed the expedition that August, and by October 1520 entered the strait that would lead him to the Pacific and then bear his name. So circuitous was the passage that Magellan had to divide his ships to reconnoiter parts of the strait. His largest ship instead deserted Magellan, sailing back to Spain. After more than a month, Magellan's remaining three ships at last navigated through the strait and into the Pacific Ocean.

The way to the Indian Ocean now lay open, but Magellan ultimately had little chance to rejoice. Anchoring off the island of Cebu in the Philippines, Magellan and his most loyal men went ashore in April of 1521, lured there by the king of Cebu on the

pretense that he was Christian and wanted Magellan's help in ridding the island of heathens. The natives instead attacked Magellan. Covering the retreat of his men, Magellan was wounded repeatedly and bled to death. Of the remaining three ships, two were in such poor condition that the crew abandoned them. Only eighteen survivors returned in the last ship to Seville, Spain, on 8 September 1522, completing the circumnavigation of the world Magellan had begun nearly three years earlier.

Mahavira

(c. 599–527 BCE)

INDIAN RELIGIOUS LEADER

The historical significance of the Indian religious leader Mahavira—who lived in the sixth-century BCE, a time when India society was rooted in the inequity of its caste system and relied for its well-being on the widespread use of slavery and the large-scale sacrifice of animals—lies in his revolutionary worldview of amity and harmony with all living beings. His teachings became the foundation of one of the world’s oldest religions, Jainism.

The Indian religious leader Mahivira lived in the sixth century BCE. Two of his core teachings—the principle of ahimsa (nonviolence) and the philosophy of *anekanta* (many-sided reality)—have universal significance and are relevant to contemporary inquiries in peace building, ecology, bioethics, and animal rights. His teachings are also the basis of the canonical literature (*Agama*) of Jainism, which not only plays a significant role within the religion but also is regarded as a primary source for understanding the history of ancient India.

Jainism regards Mahavira as the twenty-fourth *tirthankara* (ford maker) or *jina* (spiritual

conqueror). Having overcome attachment and aversion he attained omniscience and preached the way to overcome worldly suffering and attain *moksa* (liberation from the cycle of rebirth). Jainas (the followers of the *jina*) use the epithet “Mahavira” (great hero) instead of his given name, Vardhamana, and follow his adherence to ahimsa in thought, word, and deed amid adverse circumstances.

Vardhamana was born to mother Trishala and father Siddhartha, members of a royal clan, at Kundagrama in the ancient kingdom of Vaishali near the modern city of Patna in eastern India. His parents were followers of Parshvanatha, the twenty-third *tirthankara*, who is said to have lived during the ninth century BCE. At age thirty Vardhamana renounced his kingdom and became a mendicant practicing austerity in search of enlightenment for thirteen years.

Throughout this period he frequently fasted, sometimes for long periods of time and often without even water. During the thirteenth year Mahavira attained *kevalajnana* (infinite knowledge) and became omniscient. For the next thirty years Mahavira taught about ahimsa and compassion and attained nirvana (liberation) in 527 BCE.

Although ahimsa was recognized as a virtue in the Vedas (Hindu sacred writings), such recognition remained a mere scriptural knowledge. In reality Vedic society during

Painting of Mahavira (dated to 1900), whose teachings became the foundation of Jainism. Photo of painting by Jules Jain.

Kill not. Cause no pain. • Mahavira (c. 599–527 BCE)

Mahavira's time operated on a fundamental inequity rooted in the caste system and relied for its well-being on the widespread use of slavery and the large-scale sacrifice of animals (*yajna*). In this context Mahavira's teachings were revolutionary. He taught the true meaning of ahimsa and compassion. A precondition of the practice of ahimsa, according to him, is knowledge of the various forms of life: earth, water, fire, wind, vegetation, and mobile beings with two or more senses. Equally important is the awareness that in essence all living beings, regardless of their life form, are equal; all experience pleasure and pain; and all desire to live. Violence against others, in his view, is violence against oneself. This sense of our being the same as other beings, explained Mahavira, is at the core of compassion and nonviolence. Therefore, he preached the principle of universal amity and friendship. Salvation of the self, according to Mahavira, is deeply connected with one's concern for universal well-being. Every thought, word, and deed has a result and creates happiness or suffering for oneself and for others.

In addition to the virtue of being nonviolent, Mahavira emphasized the virtues of telling the truth, not stealing, being celibate, and not being possessive. He prescribed these as the *mahavrata* (great vows) for mendicants; lay Jains may observe these vows in a limited manner as *anuvrata* (small vows).

Mahavira's philosophy of understanding reality with respect to a given context (*naya*) became the basis for the Jain philosophy of *anekanta*. Jains not only evolved their own theory of knowledge (*anekantavada*) in the context of their metaphysics and ontology (a branch of metaphysics concerned with the

nature of being), but also, more importantly, were concerned about questions such as, "What constitutes valid knowledge, and how is such knowledge acquired?" In the latter sense the philosophy of *anekantavada* allows room for multiple views of reality and reduces conflict often arising from absolutist views of reality. Based on Mahavira's teachings of ahimsa and *anekanta*, Jains observe vegetarianism, reject the slaughter of animals for human consumption, and, in the context of world religions, advocate harmony and peace, acknowledging the equality of all spiritual traditions. Many people see Mahavira's emphasis on simplicity and *aparigraha* (nonpossession, nonattachment) as a valuable antidote to the rising culture of consumerism at a global scale.

Malaria

Malarial fevers have been a scourge of humanity throughout much of the inhabited Afro-Eurasian landmass, ever since they emerged from Africa with migrating humans as many as 100,000 years ago. Historians of disease estimate that malaria has probably killed more people than any other disease.

Malaria, one of the oldest diseases afflicting human beings, is a parasitical infection of the blood that produces high fevers and debilitation. It first emerged in Africa, and as human beings migrated outward approximately 100,000 years ago, they brought malarial infections with them.

Early migrants crossing the land bridge from Asia into North America at the end of the last ice age apparently did not sustain the chain of infection, and it is generally held that malaria became established in the Western hemisphere following European contacts with the New World in the late fifteenth and early sixteenth centuries. Malaria became the first truly global infection that was carried by a vector (an organism carrying a pathogen)—in this case, the mosquito, and today the parasitical infection is found in a broad tropical band that stretches around the globe.

There are four species of single-celled microorganisms (*Plasmodium falciparum*, *P. vivax*, *P. malariae*, and *P. ovale*) that live in both anopheles mosquitoes and human beings and that cause malarial infections in human beings. The most common form outside of tropical Africa, vivax malaria, is also the most widely distributed. The most common form in tropical Africa, falciparum malaria, is the most virulent. All four types of parasite are transmitted

to human beings via the bite of the female anopheles mosquito. One part of the parasite's life cycle takes place within the female mosquito; another part takes place within the human being. Because there are different malarial parasites and many different subspecies of anopheles mosquitoes, the ecological conditions that support malarial infection vary from one microecology to another; therefore, the global picture of malarial infection can be described as a mosaic of local infections.

League of Nations Malaria Investigation Committee to India. A British doctor in India holds a young child whose spleen is drastically enlarged by malaria (c. 1929). Library of Congress.

The malaria mosquito inhabits a broad band of tropical climate that stretches around the globe.

Most anopheles mosquitoes breed in standing water. Low-lying marshy areas and the edges of streams and rivers have long been associated with danger to human health, and malaria was probably one of the earliest scourges of the river-basin civilizations, such as the Nile, Tigris-Euphrates, Indus Valley, and Huang (Yellow) River. Malaria is also associated with environmental transformation. The cutting down of forests to create arable land often provides a suitable habitat for the breeding of anopheles mosquitoes. Infected people or animals, even during short visits, are able to introduce the parasite into the new environment and establish the disease. It is likely that malaria spread outward from the river-basin civilizations into other early agricultural societies.

Both European and African immigrants introduced malaria to the Americas, and the disease

became one of the most severe public health problems in the hemisphere. The incidence of malaria in the middle latitudes of North America and Western Europe decreased markedly during the twentieth century, however. In North America this was achieved through public health interventions such as the installation of window and door screens, chemical therapy (with quinine and, later, synthetic antimalarial drugs), the use of mosquito larvicides, and the draining of mosquito habitats. In Western Europe the extension of mixed farming systems is largely credited with the reduction in infection; there, anopheline mosquitoes began to take their blood meals primarily from domesticated livestock, which are not susceptible to the disease. Malaria continues to be a significant problem in South and Central America, South and Southwest Asia, the Western Pacific, and Africa. Over the course of the twentieth century, the annual number of deaths from malaria has risen in Africa, which is today the global center of malarial infection.

Following the outbreaks of epidemic malaria during World War I, the League of Nations established a commission to survey the global status of the disease. Malariologists were enthusiastic about the prospects of reaching malaria sufferers and providing them with quinine to relieve their symptoms and break the parasite's life cycle. These hopes proved elusive, however, as the global demand for quinine greatly outstripped the supply.

Following World War II, malariologists turned their attention to the destruction of the mosquito vector, and a major World Health Organization initiative was launched to spray DDT to eliminate the anopheles threat. This was initially successful, and the global rates of infection plummeted—until the overuse of DDT produced resistance in the mosquito population.

Since the 1970s, malarial parasites have become increasingly resistant to synthetic antimalarial drugs. Synthetic antimalarials in combination with artemisinin, a natural product long used in China, is currently the best hope of the medical community for fighting the disease. Considerable attention has also been

Quinine was one of the medicinal poisons; one of the strongest of these. Four grammes could make one deaf and giddy and short-winded; it acted like atropine on the visual organs . . . it was as intoxicating as alcohol; workers in quinine factories had inflamed eyes and swollen lips and suffered from affections of the skin. • **Thomas Mann (1875–1955), from *The Magic Mountain***

focused on the efficacy of insecticide-impregnated bed nets that protect against the mosquito's bite.

Mali

Stories of Mali's origins were handed down through oral history, many of which were transcribed by the North African scholar Ibn Khaldun circa the 1350s. As an empire Mali flourished in Africa from the first half of the thirteenth century to the early fifteenth century, controlling territory from the mouth of the Senegal River on the Atlantic to the salt mines of Tadmekka in the Sahara.

Preceded by the Ghana Empire and followed by the Songhay Empire, Mali was the second of the three early great empires of the western Sudan and was a dominant power below the Sahara Desert. The ancient heartland of the empire occupied a relatively compact region of the upper Niger River and its tributaries in what is now northeastern Guinea and southern Mali. But at the height of its powers during the fourteenth century, scholars believe, the Mali Empire controlled territory from the mouth of the Senegal River on the Atlantic coast eastward to include the kingdom of Gao and the salt mines of Tadmekka in the Sahara.

Beginnings

By the end of the eleventh century the decline of the Ghana Empire left a vacuum, which made possible the rise of the Soso, a southern group of the Soninke people. According to oral tradition Soso rulers belonged to the Kante clan, under which the Soso extended their authority over their neighbors and reached the height of power during the reign of Sumaworo Kante early in the thirteenth century. The former territories of Ghana at the desert edge and those of the

Mande chieftaincies in the upper Niger River region to the south came under Sumaworo's rule. Toward the middle of the thirteenth century, after a successful rebellion against Soso domination, the Mande chieftaincies unified under the leadership of Sunjata Keita and established what would develop into the Mali Empire. The transfer of hegemony (influence) from Ghana to the Soso and then to Mali marks a gradual shift of the political center of gravity southward from the edge of the Sahara to the more fertile savanna and the waters of the upper Niger River. In addition to gaining control of important long-distance trade routes running from south to north and west to east, Mali had access to extensive sources of both iron and gold in the south and salt mines of the Sahara in the north.

Oral Tradition and Mali's History

The history of Mali's origins comes from Muslim scholars of the fourteenth to sixteenth centuries, but much of what has entered the literature derives from oral tradition for which no independent confirmation exists, and it is therefore problematic in terms of Western academic standards of historiography (the writing of history). The epic narrative of the central hero Sunjata and his contemporaries in Mande oral tradition illustrates the Mande people's own view of the glorious past. It credits their ancestors with establishing one of the great empires of the medieval world, but the historical accuracy of specific details is impossible to gauge.

The principal Mande clans frame their identities in terms of descent from the founding ancestors, who are recalled by professional bards (*jeliw*) who narrate

The Sankoré Mosque, shown in Timbuktu, Mali, in 1984, allegedly dates from the fourteenth century.

oral tradition. For Sunjata, who is credited with establishing the basis of empire, an elaborate genealogy is recited and leads to his father, a member of the Konate clan. The consensus among knowledgeable informants in both Mali and Guinea identifies him as the ruler of Konfara. As Maghan Konfara (king of Konfara) he is said to have ruled from the town of Farakoro, which appears in his more complete name, “Farako Manko Farankonken.” Konfara’s supposed location on the Kokoro River near the present-day border of Guinea and Mali would position it to control the gold fields of Bure and also account for its particular importance among the other pre-imperial Mande chieftaincies. Scholars are not certain that Mali ever had a capital as the term is normally understood. Probably several major commercial entrepôts (intermediary centers of trade and transshipment) existed, and the seat of government was wherever the *mansa* (king) was in residence. At the time of the Mande’s defeat of its Soso oppressors, possibly in the 1230s, a place called “Dakajalan” is said to have been Sunjata’s center of operations. Much later, perhaps during the fourteenth century, the town of Niani on the Sankaran River apparently became an important administrative or commercial center.

In Mande traditional narrative the bards begin with episodes describing how the hero’s mother, Sogolon Conde, and his father, Maghan Konate of Konfara, are brought together to produce Sunjata, the child of destiny. Deadly conflict between Sogolon

and a jealous co-wife (whose son Dankaran Tuman is Sunjata’s rival half-brother) eventually drives Sogolon into exile with Sunjata and his siblings. The collective Mande chieftaincies subsequently fall under the tyrannical rule of Sumaworo, king of the Soso. Desperate for a powerful and effective leader, the Mande people send a delegation to bring Sunjata back from exile. With the support of various legendary figures still recognized as important ancestors, Sunjata organizes a rebellion that defeats Sumaworo and his Soso army, unifies the old Mande chieftaincies, and establishes the foundations of empire. Writing during the fourteenth century, the North African scholar Ibn Khaldun was acquainted with the existence of Soso as an intermediate kingdom between Ghana and Mali. He refers to Sunjata as “Mari Jata,” which is one of several names used by traditional bards to praise the hero. Citing oral informants of his day, Ibn Khaldun wrote that Mari Jata conquered the Soso and ruled for twenty-five years.

Sunjata’s Successors

The quality of Sunjata’s successors was uneven, with Mali enjoying times of prosperity and expansion under capable rulers but periodically enduring dismal leadership and political instability. According to Ibn Khaldun, Mari Jata (Sunjata) was succeeded by his son Mansa Uli, who was described as a great king who made the pilgrimage to Mecca in Saudi Arabia during the reign of al-Zahir Baybars, the Mamluk sultan of Egypt (1260–1277). A later ruler, the insane Khalifa, was assassinated because he shot arrows at his people and killed them for sport. By late in the thirteenth century the royal Keita line had become so weak that the kingship was usurped by a former slave named “Sakura,” who restored Mali to its former power but died while returning from pilgrimage in about 1298. After Sakura the throne reverted to two more descendants of Sunjata successively before passing to Musa, a descendant of one of Sunjata’s brothers.

People have described the twenty-five years of Mansa Musa’s reign as the golden age of the empire

of Mali. He consolidated control of lucrative trade routes and established embassies in North Africa. He also expanded the empire to include the kingdom of Gao on the eastern bend of the Niger River and valuable salt deposits in the Sahara. Musa brought wide recognition to Mali through his famous pilgrimage to Mecca of 1324–1325. Accompanied by his wife, Inari Kanute, and more than a thousand subjects, Musa arrived in Cairo in July 1324 and created a sensation through his generous gifts of gold, including fifty thousand dinars (gold coins) to the sultan of Egypt to announce his arrival. After completing his pilgrimage to Mecca, Musa returned to Mali accompanied by an architect from Spain who went to live in Timbuktu (Tombouctou) in Mali, as well as four Muslim dignitaries from the tribe of Quraysh (the Prophet Muhammad's people) who settled permanently in Mali with their families.

When Mansa Musa died in 1337 his son Mansa Magha succeeded him, but Magha died after four

years and was replaced by Musa's brother Sulayman. Mansa Sulayman was a powerful ruler who held together the vast empire that his brother had consolidated. The North African traveler Ibn Battuta visited Mali during Sulayman's rule in 1352–1353 and said that travel in the country was safe but that Sulayman's subjects disliked him. Ibn Battuta met Sulayman and later wrote a detailed description of the splendors of the Malian royal court. Ibn Battuta witnessed an episode when Kasa, the king's senior wife, apparently plotted with Jata, a son of Mansa Magha (Mansa Musa's son), to overthrow her husband. Mansa Sulayman averted the coup d'état but died seven years later in 1360.

Decline of the Empire

The Mali Empire had reached its zenith under the rule of Mansa Musa and Mansa Sulayman, but in 1360, the year of Sulayman's death, civil war broke out between his family and that of his deceased brother Musa. After much bloodshed Jata, the grandson of Mansa Musa who had plotted the coup d'état with Sulayman's wife Kasa, prevailed over his rivals and succeeded to power as Mari Jata II (1360–1373). He proved to be a tyrant, and his despotic rule seriously damaged the empire and ushered in thirty years of governmental dysfunction during which court officials sometimes attempted to restore order by seizing control from incompetent members of the royal lineage. In 1390 power was finally restored to a descendant of the original branch of the dynasty founded by Sunjata, but by that time the great days of the Mali Empire had passed. Early in the fifteenth century Mali lost control over the salt mines in the Sahara and the important trading and intellectual centers of Jenne and Tombouctou, which by the mid-fifteenth century would fall under the control of the expanding Songhay Empire.

Malthus, Thomas

(1766–1834)

BRITISH POLITICAL ECONOMIST

In the late eighteenth and early nineteenth centuries the British scholar Thomas Malthus developed theories about economics and the dangers of population growth that countered the prevailing European view of an improving society. His ideas continue to inspire thinking in ecology and environmental studies, such as the concepts of “carrying capacity” and “global commons.”

Thomas Robert Malthus, the British scholar who provided one of the first warnings of the dangers of overpopulation, put the “dismal” in the “dismal science” of political economy. Malthus’s simplistic mathematical models and common-sense observations made his dire predictions about a crowded, starving world a popular fear for generations after his 1798 *An Essay on the Principle of Population*.

Malthus was born of well-to-do English parents. He studied mathematics at Jesus College, Cambridge, taking holy orders, and eventually becoming the first professor of political economy in England at the East India College. In answer to the inevitable question posed to the “father” of population control, he had three children, two of whom survived to adulthood.

Malthus’s fame, ironically, arose from his anonymously published *An Essay on the Principle of Population, as it Affects the Future Improvement of Society with Remarks on the Speculations of Mr. Godwin, M. Condorcet, and Other Writers*. Malthus’s essay is best understood as a critique of French Enlightenment ideas of progress promulgated by, amongst others, his father, William Godwin, and Condorcet. Where these *philosophes* saw inevitable progress, Malthus saw vice, misery, and starvation. After making some

general observations about the fecundity of plants and animals compared to the relative scarcity of the means of subsistence, Malthus went on to offer a mathematical illustration to ground his thoughts on overpopulation. Malthus claimed that whereas population can increase geometrically (e.g., 1, 2, 4, 8, 16 . . .) agriculture is limited to arithmetic increases (e.g., 1, 2, 3, 4, 5 . . .). The result of these differing mathematical limits was that unchecked population would inevitably outrun the food supply. The first edition of *An Essay on the Principle of Population* was indeed a grim document, a stinging tonic to Enlightenment optimism whereby the iron laws of human nature and agricultural productivity trapped humankind in a vicious circle of starvation. By the second edition of his essay in 1803 Malthus offered the meager hope that perhaps humans might shape their destiny through delay of marriage—the only safe (morally and physically) means he could conceive of to prevent conception. Yet overall the Reverend Malthus’s population sermon remained the same: moral restraint was the only possible check to humanity’s natural tendency to succumb to animal passion, vice, and despair.

Long a mainstay of economic doctrine, Malthus’s influence on the life sciences was, if anything, more pronounced. Both Charles Darwin and Alfred Russel Wallace credited Malthus with providing the mechanism for their near simultaneous co-discovery of evolution by natural selection. Malthus’s claims for fecund parents and limited natural resources seemed the ideal engine to drive natural selection. Malthus’s links between social class and wanton breeding was also a mainstay of later social Darwinians who shared some of Malthus’s prejudices against the lower classes and assistance to the poor.

The power of population is indefinitely greater than the power in the Earth to produce subsistence for man. • **Thomas Malthus (1766–1834)**

John Linnell, *Portrait of Thomas Robert Malthus (1766–1834), Political Economist* (detail of original, 1833).

In the environmental sciences Malthus was no less influential. His population ideas seem directly linked to the later idea of “carrying capacities.” In a more popular vein, Malthus provided the intellectual impetus for a Cold War generation of “neo-Malthusians” who once again saw a growing population as the portent of doom. Garrett Hardin was a rigorous hard-hearted cynic in the Malthusian vein whose

classic essay “The Tragedy of the Commons” (1968) noted the ecological pitfalls of unchecked population growth, puncturing the optimism of 1960s liberalism as gleefully as Malthus debunked the Enlightenment. Paul Ehrlich’s *The Population Bomb* (1968) enjoyed the popular force of Malthus’s original essay through its striking mathematical predictions and evocative metaphor of exploding numbers of babies in an increasingly unstable world. In the twenty-first century, there are more than six times as many humans on the planet as the billion souls who so troubled Malthus at his death in 1834, and the debate he began remains contentious. Ironically, for this most influential of population control advocates, his intellectual progeny were numerous.

Manichaeism

Manichaeism was a religion founded in Mesopotamia during the first half of the third century CE; it incorporated aspects of Zoroastrianism, Judaism, Christianity, and Buddhism. While almost universally attacked by the mainstream religions of the West, the teachings of Manichaeism came to shape debates within the Abrahamic traditions concerning the nature of good, evil, humans, and the world.

Manichaeism was founded by Mani (or Manes; 216–276 or 277 CE), a Persian prophet who proclaimed himself “the messenger of God come to Babel” and the Paraclete (Holy Spirit). He held that God had revealed himself at various times and places in human history: as the Buddha in India, Zoroaster in Persia, and Jesus in Palestine. Mani believed that each of these figures taught that the path to salvation came through gnosis (spiritual knowledge) rather than through faith or acts. In 242 Mani set out to disseminate his message publicly, traveling extensively in Central Asia and, according to some sources, visiting India and China. While only fragments of his written works survive today, they reveal that Mani certainly had familiarity with the Christian synoptic Gospels and the epistles of Paul, Jewish Orthodox and noncanonical texts, Zoroastrianism, and Mahayana Buddhism. He reportedly said: “As a river is joined to another to form a powerful current, just so are the ancient books joined in my writings; and they form one great wisdom, such as has not existed in preceding generations” (BeDuhn 2000, 6). Mani’s challenges to the Zoroastrian priesthood, the Magi, led to his execution in 276 or 277.

Mani’s teachings, however, spread rapidly. By 370 Manichaean churches could be found throughout much of the Roman Empire, from southern France to North Africa. Augustine of Hippo (354–430), the profoundly influential Christian bishop and theologian, served for nine years as a Manichaean novice before his conversion to orthodox Christianity in 386. While violently suppressed in the old Roman provinces in the sixth century, Manichaeism continued to flourish in Persia and Chinese Turkestan for centuries, even becoming the state religion of the (Chinese) Uighur Empire (eighth century to mid-ninth century CE) in 762. In western Europe, especially France, a significant revival of Manichaeism occurred in the eleventh to thirteen centuries. It was labeled the Albigensian heresy and its challenge to the Roman Catholic Church was perceived as so great that Pope Innocent III (reigned 1198–1216) ordered a crusade against the “scourge of God,” bringing a violent end to the movement in the West. In China, Manichaeism persisted until 1600.

Beliefs and Cosmology

Like the Zoroastrian and Gnostic belief systems that influenced it, Manichaeism portrays the universe in radically dualistic terms. The universe is constituted by two oppositional forces: light and darkness. Light corresponds to the spiritual realm, the realm of goodness. Darkness corresponds to the material and bodily realm, which is evil. History is to be played out in three stages: a golden age when the realms of darkness and light are distinct and separate; a middle age in which light and darkness battle for control of

the universe; and a final age in which the realms again will be separated, with the spiritual returning to the realm of light and the material being relegated to the realm of darkness. We presently are in the middle age, the time of the great cosmic battle between the forces of good and evil.

The realm of light is ruled by and equated with God, who is known as the King of Light or the Father of Light. The material realm is ruled by an independent and powerful Archon (God) of Darkness, or Hyle (matter), who uses the process of creation to trap light in a fleshly cell. The two gods are in cosmic battle, with the universe as their battlefield. Christ, the Buddha, and other prophets came to earth to impart to humans knowledge of how to release the light imprisoned within the material realm by the God of Darkness. In some Manichaean depictions, the creator God of Genesis *is* the Archon of Darkness, and Christ is the serpent in the garden, imparting good knowledge to Adam and Eve as a path to liberating the light. In China, Mani himself became known as the Buddha of Light.

Manichaean dualism and its resulting cosmic war are used to account for the existence of evil in the world: evil emerges in this realm when the Archon of Darkness wins a battle over the good, but not omnipotent, King of Light. All material creation is evil in its very conception. Humans, being spirit incarnate, are in a tragic and flawed state, subject to evil and ignorance through the imprisonment of their spiritual essences in fleshly bodies.

Prescriptions and Practices

Because during this life humans live in the corrupt, material realm, Manichaeism attempted to separate them from the actions of the Archon of Darkness as much as possible. Manichaean clergy (the Elect) were held to the highest standards of purity: sexual abstinence (since each new birth constituted another spirit imprisoned in the flesh and hence a victory for the forces of Darkness), vegetarianism (since meat was judged to be more highly impure than vegetables),

This Manichaean icon incorporates aspects of Zoroastrianism, Judaism, Christianity, and Buddhism.

refusal to participate in food preparation (since the chopping of even vegetables harmed the light trapped within them), and abstinence from all forms of violence against human or animal (for the spiritual light could be liberated properly from living entities only by knowledge, not by slaughter).

Of these priestly prohibitions (likely a reflection of the influence of Buddhism), only the dictate against all forms of killing was required equally of the Manichaean laity, making Manichaeism a completely pacifistic religion in theory. The actual practice was somewhat different, with Manichees who fell short of the ascetic ideals often attributing their failings to a determinism resulting from their role as pawns in the cosmic battle between the forces of light and darkness.

Manichaeism Today

In contemporary intellectual discussions, Manichaeism is most often used as a pejorative term, describing a radical dichotomy between good and evil that allegedly misconstrues the nature of reality. The U.S. Conference of Catholic Bishops, for example, writes that it is “a Manichean heresy to assert that war is intrinsically evil and contrary to Christian charity” (National Conference of Catholic Bishops 1983, 162). The historian Bernard Lewis claims that the tendency of some forms of modern-day Islam to demonize Christians and Jews as “enemies of God” is attributable to Manichaeism’s influence on Islam. Whether such accusations are fair or not, the Manichaean

depiction of the world as a place of cosmic conflict between the forces of the spirit and those of the flesh doubtless has had a profound influence on modern Jewish, Christian, and Muslim discussions of humans and the world.

Manioc is a perennial shrub with tuberous roots that are valued for their carbohydrate content. Its leaves are a good source of vitamins A and B; they are also protein-rich and thus valued where protein sources are limited. Manioc is also used as a source of starch in the food, textile, paper, and other industries to produce glucose, monosodium glutamate, adhesives, plywood, and veneer.

The manioc plant (*Manihot esculenta* Crantz sub-species *esculenta*) is also known as “cassava” and “mandioca.” Some authorities suggest that there are two separate species: bitter manioc (*M. esculenta*) and sweet manioc (*M. palmata*). The U.N. Food and Agriculture Organization (FAO) disputes this, stating that the degree of bitterness, a factor relating to toxicity, varies geographically. Manioc is a member of the spurge family (Euphorbiaceae) and is a perennial shrub whose tuberous roots are valued for their carbohydrate content. Manioc is grown in agricultural systems that range from subsistent (providing food/fiber only for the farmer and his/her family) shifting cultivation to permanent cash-cropping in developing countries. It grows well up to elevations of 2,000 meters and tolerates low rainfall and nutrient-poor soils. Prior to consumption, bitter manioc must be boiled and pressed to remove cyanide compounds that are toxic to humans. The tuber is used to make flour, meal, flakes, and tapioca and may be fermented to produce an alcoholic drink. The leaves are consumed as a vegetable and are a good source of vitamins A and B. They are also protein-rich and thus valued where protein sources are limited. Manioc is dried to produce chips, and compressed pellets are used

for animal feed. It is utilized as a source of starch in foodstuff, textile, paper, and other industries to produce glucose, monosodium glutamate, adhesives, plywood, and veneer.

Manioc domestication and the crop’s subsequent spread are not well understood. Precisely where and when domestication occurred is unclear, and why it was domesticated is especially enigmatic because

Manioc (cassava) tubers provide carbohydrates for human diets and starches necessary to produce textiles, adhesives, and plywood.

I do not know that any writer has supposed that on this Earth man will ultimately be able to live without food. • **Thomas Malthus (1766–1834)**

of its toxicity. Five species of *M. esculenta* have been identified as the closest wild relatives of domesticated manioc, and *M. esculenta* Crantz subspecies *flabellifolia* (Pohl) and possibly *M. esculenta* Crantz subspecies *peruviana* (Muell. Arg.) Allem are the most likely progenitors. All are natives of Brazil and are present in western and southern Amazonia in forested areas and agricultural lands that have replaced humid forest. This environment could have been a primary locus for manioc domestication. One obstacle to pinpointing the source area, as for other root/tuber crops, is the susceptibility of root/tuber remains to decay, especially under humid tropical conditions. Thus remains are not well preserved in soils, sediments, or archeological contexts. Moreover, manioc may have been selected for purposes other than food; its cyanide content may have become valued as a poison with which to acquire fish, and the residual mash may have been recognized as a source of carbohydrate.

Portuguese invaders in the 1500s recorded that manioc was a staple crop of Brazil's indigenous peoples. From South America it was introduced to the west coast of Africa; it then spread into the humid interior, reaching the Congo River basin by about 1700. By 1800 the crop had spread to east Africa,

Madagascar, and then to Asia. The significance of manioc for the twenty-first century is reflected in the following FAO data: in 2000 the area planted was 17 x 106 ha; this produced 177 x 106 tons. The largest producers are Brazil, Nigeria, Democratic Republic of Congo, Indonesia, and Thailand. Manioc cultivation and consumption are likely to increase in the future for commercial and subsistence purposes; the latter will predominate in Africa as populations rise, although increasing use of manioc products in cities will also be important.

Manorialism

In basic terms preferred by most historians in the twenty-first century, *manorialism* defines one variant of the lord–peasant relationships that have existed throughout world history and is restricted to use in a medieval European time and place. It most commonly refers to the legal subjection of unfree peasants or serfs who were tied to the land they farmed, and who owed labor services to the lord.

Manorialism is the organization of rural economic production and socio-political relationships that characterized large parts of medieval western and central Europe from perhaps as early as the seventh century through the fifteenth century, with important aspects of the organization surviving until the French Revolution. The term comes from the division of rural land into manors, local legal jurisdictions subject to a lord (*seigneur* in French), whence the roughly equivalent term *seigneurialism*. The lord exercised legal and economic rights over the labor and produce of the peasant population living within the boundaries of his manor. Whether manorialism existed in other parts of the world—as a phenomenon, an ideal type, or a stage of development—is a vexing question in the writing of world history and complicates any assessment of manorialism in world history.

Characteristics of Manorialism

The basis of manorialism was the legal relationship of lord to peasant, which came in two basic forms. The first form, the one most closely associated with the word, was the legal subjection of unfree peasants

or serfs who were tied to the land they farmed and owed labor services to the lord. The second form, free peasants who rented from the lord, however, regularly constituted at least a portion of the population of most manors.

These two types of people were associated with three types of land that made up manors. First, *demesne* land was the part of the manor controlled directly by the lord. Its produce supported him and his dependents, either directly or indirectly through sale on the market. Second, dependent holdings obligated the holder to provide some combination of labor services on the *demesne*, a portion of the output of the holdings themselves, or a cash payment in lieu of either to the lord, the specific obligation varying according to the custom of the holding. Third, free peasant holdings owed monetary rent but no labor services or other dues, although the holder was still subject to the legal jurisdiction of the lord of the manor. Not every manor had all three types of land—some lords dispensed with any *demesne* holding, leasing all the land out to tenants, for example—nor was the fit between types of people and types of land always perfect. Peasants who were free in their person might hold dependent land and thus owe labor services, whereas serfs could also lease land that did not owe labor services. Manorial land types may also be divided by the use to which they were put, which might cross boundaries of individual holdings. Farming of grain and legumes occupied the bulk of most manors, but small plots were devoted to vegetable gardens, and fields lying fallow could support animals (usually pigs), which could also be grazed on forest land where the lord hunted game and on more extensive pasturage.

In addition to the income that the lord derived from the demesne and from rents, he charged for the use of large capital investments such as mills, bakeries, wine presses, and fish ponds, for the right to feed pigs in the woods, and seigneurial dues. These dues included the payment that peasant tenants owed the lord each time a holding changed hands by death (and in some cases by sale) and, above all, the income derived from the lord's court. Peasants had legal rights but paid to bring cases to court and often paid fines.

The somewhat artificial nature of manorial boundaries, corresponding to legal jurisdictions and not to the human geography of the countryside, may be seen in the fact that one manor might encompass several villages or parts of villages, whereas a village might be split between two (or even more) manors. Nor did manorial boundaries match local parish boundaries. Variation is, in fact, the constant in manorial organization because the proportions of free and unfree land, demesne, and free and unfree peasants and therefore of modes of economic exploitation differed from place to place and in the same place through time. Although the "typical" manor is thought of as belonging to a lay lord living in a manor house or even a castle, many manors were held directly by the king of the country and administered by a royal overseer (and indeed many lay lords, holding many scattered manors, employed professional managers as well), and a large number of manors were held by institutions, especially the Church. Church manors might be held by a collective such as a monastery or by an individual such as a bishop. Manorial management also reacted differently to wider economic changes. The rise of a more monetary economy during the eleventh and twelfth centuries usually stimulated a shift to rents and money payments but sometimes had the opposite effect: in much of central and eastern Europe, labor services became more burdensome over time as lords shifted demesne production to cash crops for sale in western Europe, a trend that extended well into the early modern period. Any generalizations about manorialism must therefore come highly qualified.

Origins and History of Manorialism

Manorial organization arose from the conditions of insecurity and decentralization of power that beset the Western Roman Empire from the fourth century on. In such conditions, small free farmers became more likely to commend themselves and their land to a powerful local landowner who pledged to protect his commended farmers in exchange for a portion of the produce and labor. In a period of declining

"September," from *Les Très Riches Heures du Duc de Berry*, painted by the Limbourg Brothers between 1413 and 1416. The peasants harvesting grapes work for the lord (seigneur) of Château de Saumur, shown in the background.

population such arrangements suited the powerful as well because they were able to lock in a secure labor supply for their estates and to consolidate the landholdings in particular areas. As the economy of western Europe contracted further between the fifth and ninth centuries, manorial organization also offered at least the ideal of local self-sufficiency, although few manors were ever completely self-sufficient, trading when possible for scarce necessities such as salt and metal.

The recovery of the European economy that began during the tenth century brought transformations to manorial organization. More money, increased trade, and the penetration of markets into the countryside tied most manors more and more into a hierarchical network of exchange that extended throughout western Europe and beyond. Reactions to the challenges and opportunities presented by the new economy varied but tended in the long run in western Europe to reduce serfdom and labor services in favor of a free class of peasant renters, although this reduction was balanced by the increasing burdens of serfdom in central and eastern Europe noted earlier; indeed, the changes in the two regions were linked by the market economy connecting them. The extent of the influence of market relations in western Europe by 1348 is demonstrated by the effect of the Black Death that hit that year: the resulting labor shortages led not to decreased peasant freedoms (as one would expect in a traditional society politically dominated by a coherent elite and as in fact did happen in places such as Egypt at the same time and had happened in Rome during the fourth century, as we've seen), but rather to higher wages and increased peasant freedoms. Serfdom effectively ended in England after the Black Death, and its burdens generally declined elsewhere on the continent without ending entirely. A monetized market in land and labor increasingly replaced manorial organization everywhere in strictly economic terms.

Manorialism survived the Middle Ages in the weakened form of seigniorial rights and dues. What survived of manorialism, in other words, was not the economic core but the legal structure of privilege and

political income that originally had facilitated the economic function but now lived a life of its own. This legal structure and related noble tax privileges were attacked by during the Enlightenment (a philosophic movement of the eighteenth century marked by a rejection of traditional social, religious, and political ideas and an emphasis on rationalism) by French *philosophes* under the misleading name “feudalism” and thus eliminated by the French Revolution. This Enlightenment blending of manorialism with feudalism was then compounded during the nineteenth century by the German political philosopher Karl Marx, who extended this conflation of the terms in analyzing the postclassical, preindustrial economy of Europe (and the rest of the world)—the economy of the period between the fall of Rome and the beginnings of the rise of merchant capitalism and the bourgeoisie in the sixteenth century—as the “feudal mode of production.” Unless one is using the (highly problematic) Marxist category, however, manorialism is not the same as feudalism, if the latter term has any coherent meaning. The difference may be summed up succinctly: the legal and economic relationship between free lords and mostly unfree peasants is manorialism; the legal and political relationship between free lords and free vassals is feudalism. The usually posited relationship between the two organizations is that manorialism is the economic organization that supported the political system of feudalism and that the two together constituted “feudal society.” In general, *manorialism* has been less damaged as a useful term by this blending than *feudalism* and remains a current analytic category in medieval European history.

Manorialism beyond Europe?

For world historians, however, the question remains: how useful is the term beyond the confines of medieval Europe? Undeniably some form of legal and economic relationship always tied peasants to elite classes in preindustrial societies. But do any such ties constitute manorialism? Or does a form need to share certain characteristics with the European phenomenon in order to qualify? Is a “feudal” political

structure one of the characteristics necessary to produce manorialism? The philosophical and methodological problems that such questions raise are both difficult and central to the process of studying world history.

The classic case of the extension of manorialism to a non-European society is in the history of Kamakura Japan (1180–1333), and it is tied intimately to notions of Japanese feudalism. In this case the political relationships among members of the Japanese warrior class rested on an economic base of *shoen*, or rural estates that generated income that was allotted to warriors, presumably as an analogue to the assignment of manors to European warriors for their support. But on close inspection manorialism and the *shoen* system share few similarities (nor was Kamakura Japan definably “feudal”), so use of the term creates more confusion than it sheds analytic light. Not only is the same true of other cases where manorialism has sometimes been claimed to exist, as, for instance, in Byzantium, czarist Russia, and some places in India, but also the entire intellectual approach to “finding” manorialism outside of Europe is suspect at its foundations. Of all the varied ways in which the extraction of surplus wealth from a subject peasant class by a political elite has been organized, why privilege a medieval European system in comparative analysis? The answer more often than not (for both manorialism and even more for feudalism) is simply that the European case has been studied first and most carefully and that sometimes on that basis the European case has been taken as paradigmatic (a typical example) for the world as a whole (this is the case with Marxist analysis of preindustrial economic organization globally and explains the importance of “feudalism” and its supposed mode of production to the historiography). Either one answer or the other, and especially both answers combined, are Eurocentric in the worst possible example of that historiographical disease. Taking Europe first tends to lead to “shoehorning”—fitting non-European cases into the European pattern for the sake of maintaining a comparison;

taking Europe as paradigmatic is simply untenable philosophically.

The majority of working world historians, therefore, would prefer to treat manorialism in a restricted way as simply one variant of lord–peasant relations in the scope of world history and restrict use of the term to its medieval European time and place. In this way manorialism provides valuable data for comparative studies and generalizations about lord–peasant relations but provides neither a model nor a framework for such studies.

Mansa Musa

(REIGNED C. 1312–C. 1337 CE, D. C. 1337)

RULER OF THE EMPIRE OF MALI

Mansa Musa, also called Kankan Musa, ruled the West African empire of Mali at its height. Under his reign, Mali expanded its territories and strengthened its control of West Africa's salt and gold trades.

Mansa Musa, despite his accomplishments as a ruler of Mali who expanded his empire's territory and trade, is best remembered for his extravagant hajj (pilgrimage) to Mecca in 1324, which fostered stronger diplomatic, cultural, and scholarly ties between Mali and Islamic North Africa. As a result, stories of Mansa Musa's power and wealth spread throughout the Islamic world as well as Europe, elevating the kingdom of Mali onto the world stage.

Mansa Musa's Mali emerged from the earlier empire of Wagadu (or Ghana, 300 CE–1240). Around 1050, Wagadu was invaded by the Almoravids (Berber Muslims), who swept through the Mauritanian Sahara, Morocco, and al-Andalus (Muslim Spain). After the Almoravid invasion (1054–1076), the empire of Wagadu fell apart. Around 1240, Sundiata, Mansa Musa's legendary Mandinka ancestor, defeated another regional power and former vassal state of Ghana, the Susu armies of Sumanguru, allowing Mali to emerge as the empire of Ghana's successor.

When Mansa Musa began his reign in 1312, Mali already controlled the trans-Saharan trade routes between the salt deposits of Taghaza (in the central Sahara) in the north and the gold-bearing lands of Wangara (southern savannah and forest regions of West Africa) in the south. During his reign, Mali strengthened its control of the trade routes by seizing important cities such as Gao and Timbuktu

(Tombouctou), on and near the Niger River, respectively, and Walata (in present-day Mauritania). His forces expanded westward to the Atlantic coast of Takrur (in present-day Senegal) and eastward beyond the Middle Niger.

Mansa Musa brought the western Sudan under a unified economic and legal system. Mali's successful extension of law and order came as a result of the unity provided by Mansa Musa's sponsorship of Islam. The administrators, traders, and many of Mali's urban subjects were Muslims. Islam provided a shared value system, which facilitated safe travel, especially for the Wangara gold traders, who operated freely, despite clan or territorial differences. The great Moroccan traveler Ibn Battuta (1304–1368/69), who traveled through Mali shortly after Mansa Musa's reign, marveled at Mali's great level of security.

However, Mansa Musa still ruled over a primarily non-Muslim population. During his travels, Ibn Battuta complained about the incorporation of indigenous Mandinka customs into court ceremonies, festivals, and daily life. In fact, Mansa Musa's legitimacy, in the eyes of the Mandinka, rested largely upon his descent from Mali's founder, Sundiata, who continues to be prominent in the oral traditions of Mali. Similarly, al-'Umari (1301–1349), a great chronicler from Cairo, noted that while Mansa Musa extracted tribute from the gold-producing non-Muslims of his empire, he was reluctant to force them to convert to Islam for fear of damaging his empire's economy.

Despite the blend of religious and cultural traditions present in Mali, there is little doubt concerning Mansa Musa's piety and commitment to Islam, as evidenced in his well-chronicled hajj in 1324. According to the North African historian Ibn Khaldun

This detail from the 1375 *Catalan Atlas* of the known world, drawn by Abraham Cresques of Mallorca, depicts Mansa Musa, ruler of the Mali Empire in the early fourteenth century, holding a gold nugget and wearing a European-style crown.

(1332–1406), he arrived in Cairo accompanied by a caravan that included some 12,000 servants and 80 camels laden with loads of gold dust. Al-'Umari explained how Mansa Musa's lavish spending depressed the price of gold in Cairo for the next twelve years.

While in Cairo, Mansa Musa was persuaded to visit the Mamluk sultan, al-Malik al-Nasir (reigned 1309–1340). Several Arab sources include an anecdotal account of their meeting. When asked to kiss the ground before the sultan, Mansa Musa flatly refused. However, he offered to prostrate himself before Allah, his creator. This clever compromise won him the respect of al-Malik al-Nasir. The sultan honored Mansa Musa as an equal, allowing him to sit at his side, and gave him robes of honor and the necessary provisions for his journey to Mecca.

Mansa Musa's sensational display of wealth, power, and piety helped to expand Mali's influence beyond West Africa. Under Mansa Musa, ambassadors were established in both Egypt and Morocco. Mansa Musa also brought Egyptian scholars to Mali. With the help of learned men such as the Andalusian poet and architect Abu-Ishaq Ibrahim-es-Saheli (died c. 1346 CE), Mansa Musa built a royal palace and new mosques in Timbuktu and Gao, which introduced the distinctive burnt mud brick

and wooden-post architecture found throughout the western Sudan.

North African scholars also helped to encourage the establishment of Islamic schools. Mansa Musa sent students to study Sunni Maliki Islamic law in Fez and Cairo, and North African scholars came to Niani, Timbuktu, and Djenne. This exchange of scholars laid the foundations for the creation of the great Sankore University in Timbuktu, which became famous throughout the Islamic world during the time of the Songhai Empire (flourished 1450–1591). Therefore, Mansa Musa's reign and pilgrimage were essential in the development of Islamic scholarship in West Africa.

Even in Europe, Mansa Musa's pilgrimage aroused interest. The famous *Catalan Atlas*, created by Abraham Cresques in 1375, depicts Mansa Musa seated on a throne, holding a nugget of gold. The *Catalan Atlas* announced Mansa Musa's wealth, the presence of a sophisticated state in the African interior, as well as the commercial opportunities available in West Africa.

Mansa Musa's reign brought prosperity and security to the West African empire of Mali. He skillfully administered one of the largest empires in the fourteenth-century world. He fostered enduring cross-cultural interaction with the Islamic world while still maintaining many of Mali's traditional religious and cultural practices. Through trade, diplomatic, and scholarly ties with North Africa, Mansa Musa's reign exposed West Africa to the world beyond the Sahara. Thus, Mansa Musa is considered one of the greatest precolonial statesmen in African history.

Mao Zedong

(1893–1976)

LEADER OF THE CHINESE COMMUNIST REVOLUTION

Mao Zedong (1873–1976) was a founding member of the Chinese Communist Party and the architect of China’s Communist revolution. Some of his socialist policies failed and caused much suffering and devastation for the people, but his legacy as a firm nationalist leader and the “founding father” of an independent China still inspires post-Mao generations.

Mao Zedong, reared in a middle-class peasant family in central Hunan Province, became a leading architect of China’s twentieth-century Communist revolution. Inspired by the antiforeign nationalism of the May Fourth Movement, he became a founding member of the Chinese Communist Party (CCP) in 1921. When cooperation with the Guomindang (GMD, or Nationalists) collapsed in 1927, Mao retreated to the countryside. Mao’s view that China’s peasants, as the most oppressed social class, were the most revolutionary, clashed with the more traditionalist Communist views of the other CCP leaders, who were focused on China’s rather small industrial-worker class. From 1927 to late 1934, Mao championed the peasant struggle, building with Zhu De (1886–1976) and others an army that used guerilla tactics against GMD forces. Forced to flee from their bases in southeastern China, Mao and others led the army to northwestern China on what became known as the Long March. In 1935 Mao became the chairman of the CCP, and his views on the nature of China’s revolution became dominant.

Japan’s takeover of Manchuria in 1932 and its war with China in 1937 shifted Mao’s attention from internal struggle toward the external imperialist threat. While the CCP fought anti-Japanese rear-

guard actions from 1936 to 1945, Mao formulated his theoretical views of a socialist revolution in China. He departed from traditional Marxist doctrine in the emphasis he gave to the role of peasants, but he retained the concepts of class struggle and the vanguard role of the party. His views were enshrined in the CCP’s Seventh Congress constitution as Mao Zedong Thought.

Nationalist spirit spread support for the CCP. Halfhearted attempts at coalition government in 1945 presaged civil war against the GMD. CCP victory led to Mao’s founding the People’s Republic of China in the fall of 1949. By the summer of 1950, China was drawn into Cold War struggles in Korea (Mao’s son was killed in U.S. bombing there) and fought U.N. forces to a draw, setting the stage for anti-Americanism over continued U.S. support for the GMD government in Taiwan.

Domestically, Mao turned attention to China’s socialist transformation. First on the agenda was land reform. Keeping the promise of “land to the tiller” made by the Nationalist revolutionary Sun Yat-sen (1866–1925), Mao immediately pushed policies that by 1955–1956 resulted in the basic collectivization of newly distributed land into agricultural producers’ cooperatives. Following the Soviet Union’s definition of socialism, China also achieved basic state ownership of industry by the time of the Eighth CCP Congress in 1957. While other CCP leaders, especially Liu Shaoqi (1898–1969) and Deng Xiaoping (1904–1997), were ready to consolidate early achievements, Mao, disturbed by the problems of corruption and bureaucracy, first invited then quashed criticism from intellectuals in the Hundred Flowers initiative and ensuing campaigns against those deemed

Visitors flock to Mao's tomb in Tiananmen Square, Beijing. Photo by Chris Howell.

reactionary. He argued that consolidation could result in loss of momentum, even reversal, by entrenching a new generation of elites. Mao's response, the Great Leap Forward (1958–1959), aimed at creating a “new socialist man.” Rightist intellectuals and others would be reformed through physical labor, especially at the ill-conceived backyard steel furnaces which, he promised, would permit China to overtake Great Britain in iron and steel production. This mass campaign also aimed at transferring technology to the countryside using the new People's Communes as the social, economic, and political interface with the center. Famine and failures resulting from the Great Leap created the first serious break within the CCP leadership and some disillusion with Mao among the general Chinese population.

Relations with the Soviet Union also suffered from these failed policies. Criticism of Mao's perceived departures from Soviet models resulted in Soviet withdrawal of technical experts, which disrupted major infrastructure projects. Mao retaliated by denouncing the Soviet Union for following the “capitalist road” and defended his policies as the logical next step in the world socialist movement, a position that exacerbated the Sino-Soviet split. At home, Mao condemned many within the party for taking the capitalist road and for failing to continue the revolution; in response, he launched the Cultural Revolution (1966–1976). Closing schools, mobilizing the masses, especially Red Guard youth, and using his own cult image, he hoped to create a generation of

“revolutionary successors.” Attacks on authority, however, threatened chaos. Mao sent students to the countryside to “learn from the peasants” and institutionalized the Cultural Revolution at the Ninth Party Congress, establishing Revolutionary Committees in factories, government offices, and communes.

China's admission to the United Nations, Mao's betrayal by Lin Biao (1907–1971), his intended successor, and continued Sino-Soviet border disputes prompted Mao to invite U.S. president Richard Nixon to China in 1972, despite U.S. involvement in Vietnam. From 1972 until Mao's death in 1976, ideologues, including Mao's wife Jiang Qing, tried to assert power under cover of Mao's name.

Mao's death concluded an era of radical ideological leadership in China. Official assessment of his life is that he was 70 percent correct and 30 percent in error (the same as was given to Stalin in the USSR). But Mao's legacy as a firm nationalist leader and the “founding father” of an independent China still inspires post-Mao generations. Mao's image still dominates Tiananmen Square where his preserved body lies in state. While the bodies and images of Soviet leaders have been buried and removed from public places, Mao's remains on display, and Mao souvenirs are still popular items for both Chinese and foreign tourists. Some superstitious Chinese claim magical protective qualities associated with the displaying of his image.

In addition to the well-known influence of Mao's ideas of “people's war” using guerrilla tactics adopted

*We must learn to do economic work from all who know how, no matter who they are.
We must esteem them as teachers, learning from them respectfully and conscientiously.
We must not pretend to know when we do not know.* • **Mao Zedong (1893–1976)**

by Ho Chi Minh in Vietnam, there are also Maoist groups such as the Sendero Luminoso (Shining Path) in Peru, the Naxalite movement in India, and recently in Nepal under the leadership of the self-proclaimed Maoist leader Comrade Prachanda, the nom de guerre of Pushpa Kamal Dahal. These have also emphasized Mao's strategy of a peasant-led anti-imperialist anti-bourgeois struggle for power rather than his failed economic development model.

Marx, Karl

(1818–1883)

GERMAN POLITICAL PHILOSOPHER

Karl Marx's extensive critique of capitalism as an economic and social system driven by class conflict, exploitation, and alienation—and his vision of its replacement in the logic of history by a humane, egalitarian, and democratic Communism—found worldwide resonance after his death in 1883; it fundamentally altered the way large numbers of intellectuals, workers, and peasants regarded historical change and social and political struggle.

The power of Karl Marx's critique and analysis of capitalism, and his fervent call to action to replace it with his egalitarian ideal of communism, inspired revolutionary parties and movements to overthrow governments in Russia, China, Vietnam, Cuba, Zimbabwe, and Mozambique. The success of those revolutions shaped key features of the twentieth-century world and called more attention to his writings, but Marx himself would probably not have endorsed much of what was done in his name. When he read how French Marxists were applying his ideas he told his son-in-law Paul Lafargue, "If anything is certain, it is that I myself am *not* a Marxist!" (Marx and Engels 1993a, 353).

With interests spanning philosophy, journalism, political agitation, economic theory, and satire, Marx had an astonishing capacity for rapidly assimilating everything he read and for setting his ideas on paper. In addition to keeping voluminous notebooks, he published major works in economics, philosophy, and political analysis. A profound and systematic thinker who was by nature an optimist, Marx believed that ideas should be employed to change the world and that, if theory is to be at all meaningful, theory has

to inform practice. In line with that thinking, he was active in radical politics most of his life.

As a young man, Marx studied philosophy and received a doctorate from the University of Berlin in 1841. Because his radical ideas barred him from a university career in Prussia (the largest German state), he went to work as a journalist in Cologne, but Prussian authorities closed the popular newspaper he edited in March 1843. Immigrating to Paris, he became attracted to French socialist groups and met his lifelong collaborator, the German socialist Friedrich Engels. Expelled from Paris for subversive journalism in 1845, Marx traveled to Brussels, Belgium, where he founded Communist correspondence committees and continued writing. Involved in an organization of radical artisans, in 1848 he and Engels published what became his most widely read work, the *Communist Manifesto*. In it Marx outlined his views on the necessity of economic and political revolution, the role of modes of production, exploitation and class struggle in history, and the inevitability of Communism arising out of capitalism. Soon after its publication, revolutions exploded across Europe, overthrowing or threatening governments in France, Austria, Prussia, and Belgium. Marx moved back to Cologne to edit another popular newspaper, but authorities closed it as well, and he fled Germany in 1849, finally landing in England, where he remained for the rest of his life.

Believing that fresh revolutions were about to break out in Europe, Marx wrote articles about the significance of the 1848 revolutions and was active in the Communist League in London. Disagreements about the timing of a revolutionary uprising led to a split in the league, and Marx retired from active

Portrait of the young Karl Marx, who received his doctorate from the University of Berlin in 1841.

politics for the next decade. Marx spent most the 1850s and 1860s researching history, politics, and economics in the British Library, taking volumes of notes for his monumental study of the operation and history of capital, the first volume of which he published in 1867. During this time his family lived in near poverty, and Marx declared that his dedication to finishing *Das Kapital* (*Capital*) caused him to have “sacrificed health, happiness, and family” (Marx and Engels 1993b, 366). Such an admission must have pained him greatly because his greatest joy in life was his family. A gruff and blunt public debater, Marx was considerate, generous, and playful within his family. His only regular source of income, however, was his articles on contemporary politics for the *New York Tribune*, a radical newspaper with the largest circulation in North America. Marx also received money from Engels to make ends meet, and his income would have been adequate for his family, but he and his wife, Jenny, had bouts of extravagance

and generosity that caused continual financial crises. With a sense of irony Marx would often reflect that he, who wrote so much on capital, had so little talent in managing it. In 1864 an inheritance from his mother and a bequest from a friend, along with an annuity given him by Engels in 1869, finally brought financial relief.

Marx cofounded the International Working Men’s Association (also known as the “First International”) in 1864, bringing together revolutionaries from Europe and North America who sought the overthrow of capitalism and the establishment of an economic and political commonwealth. Marx’s health deteriorated after a partial stroke in 1873, and he became less and less capable of the sustained intellectual and political effort that had characterized his life.

Marx never finished *Capital*, his life’s work. Volumes 2 and 3 were left as manuscripts, which Engels edited after Marx’s death, and the other five volumes that Marx envisaged never were even drafted. Still, Marx will be remembered for the scope of his historical and social vision as well as for his contributions to economic and social thought and to revolutionary theory and practice. As a young man he once mused, “The philosophers have only *interpreted* the world, in various ways; the point, however, is to *change* it” (Marx and Engels, 1993c, 3). His work inspired countless others to see his point.

Marxism

Marxism is an economic, social, and political theory or system based upon the philosophies of the nineteenth-century Germans Karl Marx and Friedrich Engels. Socialism and communism are particularly prominent strains of Marxist thought. Central to Marxism is the aim of achieving revolutionary social change through an ongoing class struggle between labor (the proletariat) and the owners of capital.

It has been said that the three most important ideas that shaped the twentieth century came from the English naturalist Charles Darwin, the Austrian neurologist Sigmund Freud, and the German philosopher Karl Marx. Darwin's theory of evolution and Freudian psychoanalysis both fundamentally altered humanity's understanding of itself. Marx, his ideas, and what his followers did with his ideas were among the most significant factors shaping the political and economic course of the twentieth century. While some have declared Marxism a flawed analysis and a failed ideology, the proclamation of the death of Marxism may yet be premature, as witnessed by the burgeoning antiglobalization movement.

Marx's ideas influenced not only the rise of unionized labor and the welfare state, but also the Russian Revolution, communism, socialism, and Zionism; even the ethic of the kibbutz owes a debt to Marx. The political consequences have been immense. Fascism arose as a reaction to communism, and millions of people died in World War II (1939–1945) because of it (estimates vary widely, from 50 to over 80 million, of which only about 25 million were military casualties). Following the war, the geopolitical competition between capitalism and socialism—the Cold

War roughly dividing East and West—defined the contours of world politics for the best part of half a century. The formation of the State of Israel in 1948 continues to shape the politics of the Middle East to this day. The Chinese Communist Revolution of 1949 still affects the lives of over a billion people. Worldwide, postwar anticolonial struggles for independence were often cast in the Marxist rhetoric of anti-imperialism, class analysis, and socialist revolution. But the failures of the Soviet Union either to deliver goods or to fulfill Marx's vision of a humanistic society led to its implosion in 1991. Still, Soviet Communists managed to transform a backward, rural society into a major industrial power, despite external pressures that strained its budgets and sustained dictatorships.

Despite having considerable intellectual, political, and even commercial appeal, the term "Marxist" is resistant to precise definition and is somewhat obscured by the range of interpretations laying claim to the title of "true" Marxism. Broadly speaking, Marxism refers to any form of idea that demonstrates its fidelity to the thought and influence of Marx's literary-philosophical heritage. A Marxist belief "is one held by anyone, academician or political stalwart, who thinks or can persuade others that the belief in question is in accordance with Marx's intellectual or political legacy" (Carver 1991, 23–24). Some prefer a more strict interpretation of Marxism that refuses to allow for any perceived deviations from Marx's own writings (the term "Marxian" is sometimes used to designate ideas that can be traced back directly to Marx). For our purposes, we will be content to use "Marxist" or "Marxism" to describe the general trajectory and impact of Marx's influence through his writings and his later interpreters.

Portrait of the young Friedrich Engels, Marx's lifelong collaborator.

Few thinkers have enjoyed the influence, polarizing appeal, and notoriety of Karl Marx. Marxist thought has affected every aspect of the social sciences, including religion, history, sociology, and politics, and has permeated discussions of the individual and society for almost two hundred years. Important Marxist themes include “historical materialism” (the concept that events in history are driven by economic concerns and class conflict), and the dialectic between the bourgeoisie and the proletariat.

Karl Marx: Background and Philosophy

Marx was born in 1818 in Trier, Germany, and educated in Prussia. After studying law in Bonn, he attended the University of Berlin and earned his doctorate in philosophy at Jena in 1843. Like most philosophy students at that time, he was much influenced by Georg Wilhelm Friedrich Hegel (1770–1831), the German idealist philosopher who stressed the primacy of ideas—that consciousness precedes the objects of consciousness. Encompassing theories of alienation, domination, and historical change, Hegel argued that through reason people could overcome domination and find freedom. Ludwig Feuerbach

(1804–1872), Marx's teacher, argued for a more materialistic interpretation of Hegel, rooted in human sensory experience.

Marx became a member of a group of radical students, the antireligious Young Hegelians. As a radical, he was unable to find a teaching position so, turning to journalism, he became the editor of *Rheinische Zeitung* and also served as a correspondent for the *New York Tribune*. At about this time, he met the political philosopher Friedrich Engels (1820–1895), who became his lifelong companion, colleague, and often patron. Marx's early work consisted of critiques of Hegel's idealist philosophy as removed from people's lives, and of the materialism of Feuerbach's elaborations of Hegel. Marx offered commentaries on religion and politics. One of his important early writings concerned how labor under capitalism led to alienation: how one becomes estranged from one's work and the products of that work, estranged from others, and, indeed, estranged from one's very humanity.

Marx's work proceeded to offer materialist interpretations of history and of then-contemporary French politics, such as its civil wars and the 1851 coup d'état of Napoleon Bonaparte's nephew Louis Bonaparte (who then took the reign name Napoleon III). Most important, Marx began his studies of the capitalist political economy. In 1848, he penned the *Communist Manifesto*, which would become the foundational document for Communist parties. In it, Marx offered a critique of capitalism: while he praised its power to liberate people from feudalism, he pointed to the inherent injustices of its class system and called for workers to revolt and overthrow the forces of capital. He soon moved to London where he wrote on French history, class struggle, and political economy, arguing that the eighteenth- and nineteenth-century theories of the British economists Adam Smith and David Ricardo, among others, were in fact ideologies that merely served to legitimate the activities of the bourgeoisie.

Marx observed the human species in terms of Darwinian evolution, asserting that humans are primarily “workers” (*Homo faber*) who interact with their created tools in order to survive. For Marx,

competition is not the natural state of being but rather an artificial byproduct of the capitalist system, thus producing an ongoing imbalance of materials and wealth. Within this very material struggle are the seeds of “class struggle”; certain individuals will inevitably elevate themselves above their fellow humans via their domination of the profit from their labor, creating an imbalance of power and the roots of discontent for those who are deprived of the surplus. The “privileged class” must therefore mold “consciousness itself” (i.e., human ideas about what is right/wrong or attractive/unattractive and what it is that humans should have and should want) in such a way as to benefit their unending pursuit of and mastery over surplus capital.

In 1864, socialists and communists formed the International Working Men’s Association. Its world congress in Geneva was the first Internationale, or organization of socialist groups. Marx assumed leadership of the organization and devoted a great deal of effort on behalf of workers. Marx proceeded to research and write his magnum opus, *Das kapital* (*Capital*), a book that is still widely studied and debated. If Marx had become a professor of philosophy who approached debate academically, he might have been regarded as merely the most important post-Hegelian philosopher. But the power of his intellect, the passion of his politics, and his vision of overcoming capitalism and its adversities would attract many followers seeking to change the face of politics and social life the world over. Timing is also important: at certain moments, social conditions enable certain ideas to flourish, and a leader’s influence is magnified. Such was the case with Marx.

Marxism as Theory and Praxis

Marx began writing as industrialization was rapidly changing the social fabric of Europe. While new forms of production, transportation, and finance created enormous wealth for the owners of capital, such as factories, banks, railroads, and steamships (and profited others such as wholesalers), for the great masses of peasants who came to cities in search of

jobs the working and living conditions were harsh and inhumane. Their jobs paid little, their hours were long, tenement conditions were unhealthy and dangerous—indeed, brutal. It was in this context that Marx began to criticize capitalism as not only economically exploitative but also morally bankrupt, dehumanizing, and alienating to workers. When people sell their labor on the market, said Marx, labor becomes a commodity. When people sell themselves as commodities, when they own neither the tools nor the raw materials nor the fruits of their labor, they become powerless, devoid of their humanity and shorn of community. Such people often turn to prayer, which Marx saw as the expression of “real suffering.” But religion, controlled by elites, cannot ameliorate the economic basis of that suffering, said Marx. Rather, it acts as the “opiate of the people,” promising relief in the next life and sustaining class-based oppression in this one.

In his most accessible work, *The Communist Manifesto*, Marx presented his theory of history as class conflict, his critique of domination under capital, his analysis of why capitalism should and will be overcome, and the concrete measures that would be instated upon the overthrow. The agents of history are classes and class interests, Marx argued, not individual kings, generals, or presidents, and surely not religion, political ideas, or cultural factors, all of which merely disguise ruling-class interests. He claimed that Communism represents the “real interests” of the working classes whose labor creates the wealth of the bourgeoisie. Capitalists prosper while workers are exploited and alienated. Furthermore, capital creates a *lumpenproletariat*, a surplus population of the jobless—beggars, thieves, and prostitutes.

Marx was not the first to criticize capitalism and suggest alternatives. The three primary influences on Marx were Hegel, the British political economists already noted, and the French socialists of the eighteenth and nineteenth centuries. The French socialists had deplored the living conditions of the workers and argued for communal ownership. Claude-Henri de Rouvroy (known as St. Simon) had sketched a materialist theory of history while Charles Fourier

suggested a vision in which work and play were joined and human dignity realized. Pierre-Joseph Proudhon declared that property was theft and the basis of modern misery. As a system builder like Hegel, Marx absorbed these ideas and developed a comprehensive, materialist explanation of power and ideology.

For Marx, history as commonly understood was obscured by ideologies that masked the economic and political motives of elites. He provided a way of comprehending the general misery of the poor in a broader context. In the nineteenth century, the poor were commonly seen as lazy, impulsive, and morally deficient and thereby *they*, and not the class system, were deemed responsible for their adverse conditions. In *Das kapital* Marx demonstrated the nature of exchange value (goods produced for the market to be exchanged for money as opposed to being used by the producer and/or traded for other goods), the valorization process (profit based on exploitation), and “commodity fetishism”—the way in which goods produced and sold for the market were embodiments of social relations. In so doing, Marx transformed the way people understood the world thereafter.

Perhaps the most politically salient part of Marx’s work was his analysis of capitalism’s inherent contradictions, which he thought would lead inevitably to its overthrow. Business cycles and crises of overproduction would either demand imperial expansion or create unemployment, forging workers into a revolutionary class, whose eventual victory would overturn the economic order and abolish private property. Communism would usher in an era of freedom, an order that acknowledged all people’s needs, allowing them to realize their full creative potential and find meaning, recognition, community, and empowerment.

Comprehensive and sophisticated, Marx’s analysis “put it all together” and offered an ameliorative vision that held considerable allure. For the growing masses of impoverished workers and those sympathetic with workers’ struggles, Marx provided a rationale and agenda for the revolutionary change that he thought inevitable. In the style of many great leaders, he gave people hope. The *Internationale*, the anthem of the

Communist Party, promised that a “better world was in sight.”

Marx’s Political Influence

To temper the lure of Communism, Europe’s bourgeois and monarchist governments initiated a variety of reforms in the wake of the 1848 revolutions and the brief rule of the Paris Commune in 1871. Indeed, the first social security legislation laws, unemployment compensation, and pensions were passed in Germany in 1872. Marx’s own analyses hinted at ways in which workers could be pacified by socialist reforms providing material benefits. But as wage laborers, they would remain alienated and dominated—even if less harshly. The very threat of Communism disposed the capitalist classes first to initiate reforms, unions, and entitlements (such as pensions and unemployment insurance) that would benefit the workers, and second, to promulgate ideologies such as consumerism and nationalism that would mask the class interests of the bourgeoisie as the “general good” and secure their hegemony by obscuring the operations of class.

After Germany established social security benefits, workers have been ever less than enthusiastic about toppling governments that provide unemployment benefits and pensions. (In the twentieth century, consumerism would further dull revolutionary impulses.) But Marx’s ideas and theories of revolution would be embraced by revolutionaries in preindustrial societies struggling against either colonial rule or wealthy elites.

Among Marx’s more important successors would be Vladimir Ilyich Lenin (1870–1924) and Leon Trotsky (1879–1940), who led impoverished masses of Russians and the disaffected czarist armies in a revolution to form the first major Communist government. Following World War II, Marxism inspired a number of “peasant revolutions,” the most important being the Chinese revolution led by Mao Zedong in which the Communists eventually defeated Chiang Kai-shek’s Nationalists. There were a number of other societies and revolutionaries influenced by Marxism, including Ho Chi Minh (Vietnam), Tito (Yugoslavia),

Fidel Castro (Cuba), and Che Guevara (Congo, Cuba, and Latin America). Each movement blended Marxism, nationalism, and peasant struggles into liberation movements seeking autonomy from colonial rule and/or capitalist domination; not all such movements were successful, some of them needlessly bloody and violent.

Communism as practiced in the USSR bore little relationship to Marx's vision of a just society. For a number of reasons, primarily due to the totalitarian leaders who claimed the mantle of Marx in an attempt to legitimate their tyranny, and partly due to pressures from the West, come 1991 the Soviet Union collapsed. China, meanwhile, had embraced an increasingly open market economy to become one of the most powerful countries in the world. Marx should not be blamed for the totalitarian nature of formerly existing socialism; he is no more responsible for the gulags, secret police, and political murders of these dictatorial regimes than Christ was responsible for the Inquisition. For many contemporary Marxists, the humanistic side of Marx and his critiques of alienation, exploitation, and domination remain a salient warning of the dysfunctions of global capitalism.

Marxism and the Future

Marx and Marxist thought have remained influential throughout the nineteenth and twentieth centuries through the work of thinkers and social theorists such as Max Weber, Talcott Parsons, György Lukács, Antonio Gramsci, Louis Althusser, Rosa Luxemburg, Ernst Bloch, Walter Benjamin, the Frankfurt school, Antonio Negri, and Slavoj Žižek, to name just a few prominent intellectuals. So, too, a number of feminist theorists began to see gender stratification in terms of class and ideologies of dominance—in this case, patriarchies. Similarly, while the field of economics in the twenty-first century is largely dominated by neoliberals, some contemporary economists have been much influenced by Marx, such as Joan Robinson and Richard Wolff, valuing equality and redistribution. Consequently, class analysis, the economic basis of power, and the roles of ideology, alienation,

reification, and commodity fetishism are fundamental concepts for a number of disciplines in the social sciences, arts, and literature.

The power of Marxism as an intellectual influence has often been said to be on the wane. But Marxism has been pronounced dead a number of times—even as throughout the world growing numbers of people suffer from the adverse consequences of neoliberal globalization. Marx suggested that the use of machines and the overproduction of goods would lead to economic crises; indeed, this does seem to be a serious problem requiring urgent attention in the early twenty-first century. Millions have mobilized to challenge and contest contemporary forms of global capitalism. While these movements represent the diverse interests of workers, feminists, environmentalists, gay activists, and so on, one of the common themes heard across this wide spectrum of voices is a concern for the onerous consequences of global capitalism—often articulated in Marx's language of class analysis and colored by his humanistic vision. The vast numbers of writings critical of globalized capital, the widespread antiglobalization demonstrations, and the World Social Forum under whose banner 100,000 activists and intellectuals gather regularly all affirm the continued influence of Marx as one of the most significant and important thinkers in history.

Mass Media

Mass media—modes of communications intended to reach large numbers of people—have played an important role in world history, rousing populations in various times and places to resist governmental or other oppression, and calling those in power to account.

Communications media that are geared to reaching the masses—mass media—has been a force in social, political, and cultural change throughout history. It is not surprising that in many countries rulers have refused to permit a free press, and journalists have even been killed for speaking out. In some countries the media are nothing more than the official voice of those in power, whereas in others, the media have served as the voice of resistance or even revolution.

The First Print Mass Media

Perhaps the first newspaper was the *Acta Diurna* (Daily Transactions) in ancient Rome. Julius Caesar decided to make the proceedings of the government available to the citizenry, and starting in 59 BCE, they were posted in public places. Later versions were called the *Acta Urbana* (Transactions of the City) or the *Acta Senatus* (Transactions of the Senate). These news sheets were hand-copied by scribes, probably on papyrus, and they were undoubtedly subject to government oversight and control. Good news about the Roman Empire was much more likely to appear in writing than bad news. In addition to the daily doings of those in power, the *Acta* contained birthday and wedding announcements and information about new buildings being dedicated. Later emperors expanded

the role of the *Acta*, using them to disseminate favorable stories about themselves or unfavorable stories about particular rivals. The *Acta* seem to have been very popular and to have reached a wide audience; those who could not read stood waiting until someone (a professional town crier or literate passerby) would read the news aloud. The orator and historian Tacitus (c. 56–c. 120 CE) wrote in his *Annals* that people from all walks of life eagerly read the various *Acta*, and political leaders found them an invaluable resource.

Another ancient empire that made use of something resembling a newspaper was Tang-dynasty China (618–907 CE), where the *Di bao* (Court Gazette) contained news gathered by various members of the governing elite. Originally intended for members of the imperial court, it was later expanded to include the intellectuals, but unlike the *Acta*, it was not posted anywhere that the general public could read it. By the time of the Ming dynasty (1368–1644), newspapers received wider dissemination, but the elites still wanted information restricted to a select few and wanted control over what the general public read. It was not until the 1800s that the newspaper industry in China began to flourish.

Early European News Sources

Although the Chinese inventor Bi Sheng had developed a method of printing using movable wood blocks around 1041, Europe did not make use of moveable type until Johannes Gutenberg developed his printing press around 1438.

Prior to the mid-1800s, European publications that reported on news events were called by various names.

One of the oldest forms of publication to survive is the *coranto*; the first *coranto* was published in Amsterdam in December 1620 and was more of a pamphlet than what we would today call a newspaper. Most of the *corantos* were published in Dutch. They focused on business news and on political news that might affect business. Amsterdam was a very cosmopolitan city, with merchants who traveled throughout the known world. They wanted to know what was going on in other countries where they might engage in commerce. As a result, *corantos* became very popular; at one period in the mid-1600s there were as many as eight weeklies or biweeklies, bringing news from Africa, Asia, Italy, Germany, and elsewhere.

In Italy there was the gazette, a weekly news sheet that seems to have originated in Venice in the mid-1500s (although some historians question the date, as they also question whether the sheet really took its name from the coin *gazeta* with which one paid for it). Gazettes, like *corantos*, contained business and political news and were read both by the general public and by the many merchants who came to Italy. In Germany there were weeklies as early as 1615, and a daily newspaper, the *Leipziger Zeitung* (Leipzig Newspaper), began in 1660. These newspapers covered politics, culture, and science, and provided important information during the Thirty Years' War. But the German press was frequently subjected to restrictions by the government.

In Paris, as early as 1488, there were *occasional*—government leaflets about four pages in length. Mostly published in Lyon and Paris, they were mainly brief summations of what the government was doing. From about 1529 there were also the *canards*, publications of a more sensational and sometimes polemical nature. French exiles living in Amsterdam published broadsides that criticized the intolerance of King Louis XIV; these publications were called *lardons* (“jibes”), and the exiles, mostly Huguenots, had them smuggled into France during the late 1690s. Early in 1777, Paris gained its first daily newspaper, the *Journal de Paris* (Newspaper of Paris), but the government maintained strict control over what could be printed. An underground press existed for

dissenting voices. There were also some women who participated in journalism, publishing a monthly newspaper called the *Journal des Dames* (The Ladies' Newspaper), which first appeared in 1759. Its editors believed in “the female public's right—and obligation—to be informed about controversial matters” (Landes 1988, 58–59). Unfortunately, as with other newspapers of that time, it frequently encountered government censorship, as well as resistance to its call for greater female participation in public life. It ceased publication in 1778.

In Spain under King Ferdinand and Queen Isabella, all printers had to be licensed. The first Spanish newspaper was probably the *Correos de Francia, Flandres y Alemania* (News of France, Flanders and Germany), founded by Andres de Almansa y Mendoza in 1621. In Spain's colony in Mexico, the *Gaceta de Mexico y Noticias de Nueva España* (Mexico Gazette and the News of New Spain), regarded by some as Mexico's first newspaper, appeared in January 1722, published by Juan Ignacio María de Castorena y Ursúa, who later became Bishop of Yucatan.

In England the earliest surviving newspaper, from September 1621, is the *Weekly Newes from Italy, Germany, Hungary, Poland, Bohemia, France and the Low Countreys*. It followed the format of the Dutch *corantos* and at first carried mostly business news, although gradually it expanded to include natural disasters, wars, and so forth. In 1641 reports from Parliament were issued for the first time. The first daily was the *Daily Courant*, founded by Samuel Buckley in March 1702. Magazines such as the *Tatler* also began to proliferate around this time; they offered opinions about current events. As demand for newspapers and news publications continued to increase, so did government restrictions, sometimes indirectly, through excessive taxes on printers, and sometimes directly, with dissenting presses being shut down entirely. After a brief period of relative freedom during the 1640s, when journalists could even criticize the king and hundreds of pamphlets and news sheets were seen in London, press censorship was reimposed by Oliver Cromwell in 1655. The same sort of control occurred in the British colonies. The first newspaper

in North America, *Publick Occurrences*, was published in September 1690 and was immediately shut down. The next colonial American newspaper, the *Boston News-Letter*, appeared in 1704 and had to submit itself to the British censors in order to continue publishing. It survived for the next seventy-two years by avoiding controversy and not criticizing the monarchy. Several newspapers that began in colonial times are still publishing today: the *New Hampshire Gazette* was founded in Portsmouth in 1756, and the *Hartford [Connecticut] Courant* began in 1764. European immigrants to North America from other countries also established newspapers. The first to appear, a German-language paper, was *Philadelphische Zeitung* (Philadelphian Newspaper), which was begun in 1732.

Print Media in the British Empire

Throughout the British Empire, English was the preferred language for journalism, since entrepreneurs from Great Britain founded most of the newspapers. This excluded everyone who could only read in the vernacular, but it did help any local journalists who were fluent in English to get hired. In Calcutta, India, James Augustus Hickey started the *Bengal Gazette* in January 1780. To help cover the expenses of publishing, he began taking advertisements, but the newspaper still lasted only two years, due in large part to Hickey's controversial reporting about the governor-general. Even in a faraway place, the British government took a dim view of criticism by the press. Although the *Bengal Gazette* is regarded by some as the first Indian newspaper, other sources note that in 1777 a member of the Parsi community named Rustomji Kashaspathi founded a newspaper called the *Bombay Courier*. A few newspapers in local languages did begin to emerge in the 1800s, but the most influential newspapers were English-language papers. Among the best-known was the *Bombay Times and Journal of Commerce*, founded in 1838; today it is known as the *Times of India*, a name it began using in 1851.

In Canada the first newspaper appeared in March 1752; the *Halifax (Nova Scotia) Gazette* began as a

This 1930 brochure marketed early mechanical TV as magical, amazing, and romantic—despite its tiny 2- to 3-inch screen.

two-page tabloid, with news from England, Europe, and other British colonies. Its founder was the printer John Bushell. Although it was published in Canada, it did not cover local births, deaths, or marriages until about 1769; most of what it printed at first was material aimed at government officials, merchants, and the military. More local in its focus was the *Toronto Globe* (today the *Globe and Mail*), founded by Scottish émigré George Brown in 1844. The *Globe* sent correspondents all over eastern Canada to cover the news. And in Montréal, the *Gazette* began in 1778 as a French-language newspaper, switched to a bilingual format, and finally became all English in 1822.

In Australia one of the first newspapers was the *Sydney Gazette and New South Wales Advertiser*, founded in 1803. Three British men who had worked

The free press is the mother of all our liberties and of our progress under liberty. • **Adlai E. Stevenson (1835–1914)**

there, Alfred Stephens, Frederick Stokes, and William McGarvie, went on to found the *Sydney Herald* (today the *Sydney Morning Herald*) in 1831. The *Herald*, originally a weekly and only four pages long, expanded and became a daily in 1840.

Cape Town, South Africa, had a newspaper as early as 1800; the founders of the *Cape Town Gazette* were Alexander Walker and John Robertson, and it published articles in both English and Afrikaans. There was no black newspaper in South Africa until 1884, when *Imvo Zabantsundu* (Xhosa: Native Opinion) appeared for the first time. Founded by black journalist John Tengo Jabavu, it published in the Xhosa language and English, and was unique in addressing current events and politics from a black perspective and in giving black poets and essayists a way to get their ideas into print.

Historical Censorship of Print Media

The excuse often given for government censorship of the press has been that journalism is unreliable, and in its formative years, there may have been some truth to this claim, since some of the news sheets were filled with unfounded rumors, and some writers used sensationalism to attract an audience. But the real problem for the ruling classes was that the press began taking sides in political issues. Many readers saw the newspapers as a way to learn perspectives that differed from the official version given by those in power. Then, as now, the powers-that-be sponsored “official” publications. The rulers often hoped theirs would be the only version, but in England, to give one good example, other publications developed, some of which questioned the government. There were ongoing tensions between the rulers and the publishers: rulers didn’t mind getting some positive publicity from a newspaper, such as when in 1622, King James I of Britain explained in print why he had decided to dissolve parliament. But monarchs often tried to shut down newspapers that they perceived as too critical. In France, printers and publishers were sometimes arrested and flogged for publications deemed seditious or defamatory. In at least one

case, in England in 1584, a Catholic printer, William Carter, was sentenced to death because it was believed that an allegorical story he had written in one of his widely disseminated books was really an attack on the queen’s Protestant faith.

Despite the best efforts of various European monarchs to muzzle the press, journalists continued to make their opinions known, and as the years passed, reporters and columnists showed they could shape public opinion. In England the influence of the press grew so much that by the early 1800s, British journalists were being referred to as the “fourth estate,” in reference to the three classes (or estates) of society: the nobility, the clergy, and the common people. It was suggested that in addition to the original three, there should be added a fourth, the journalists, who were in some ways the most influential of all, since their telling of a story could bring praise or disapproval from thousands of people.

Freedom of the Press and Sensationalism

The idea of freedom of the press was advocated by scholars and poets from at least as early as the poet John Milton’s famous *Areopagitica: A Speech for the Liberty of Unlicensed Printing* to the Parliament of England, in 1644, but it wasn’t until the mid-to-late 1700s that any countries created laws to formally protect journalists. Scandinavia led the way in 1766, with Sweden being the first country to abolish censorship and introduce a law guaranteeing freedom of the press, followed by Denmark and Norway in 1770. Freedom of the press became part of the newly independent United States’ Bill of Rights—the first ten amendments to its constitution—which was ratified in 1791.

Earlier centuries had seen the occasional publication of unfounded rumors or sensationalist stories, but in the nineteenth century, as newspapers proliferated, so did some of those excesses. Perhaps the most disturbing was “yellow journalism.” Named after a character in a U.S. comic strip, the “Yellow Kid,” in its milder forms it was just a preoccupation with

scandal, rumor, and sensationalism. The Canadian journalist James Creelman was well known in the late 1800s for his dramatic and hyperbolic writing. As a correspondent for several New York newspapers, he reported from dangerous places, while interviewing some of the most controversial newsmakers of his day in a “you are there” style. The style of writing was very exaggerated and filled with words that made it seem as if the writer was in mortal danger just for writing the story. Creelman was what his age would have considered shocking—when he wrote about atrocities during the Sino-Japanese war, for example, his narratives were so graphic that people could not believe such horrible things were true. He was among that era’s best known correspondents, and saw himself as a truth-teller. In England, William T. Stead, the publisher of London’s *Pall Mall Gazette*, reacted against what he saw as the blandness of the British press by creating a strategy to appeal to the working-class person rather than the educated elite. He began using screaming headlines and more illustrations, as well as actively crusading against a variety of social problems that affected the poor; for example, in the mid-1880s, the *Gazette* did a series on child prostitution, at that time called “white slavery,” showing how easy it was for poor children to be exploited. At that time standards were quite different, and even writing about prostitutes was considered in questionable taste. The pages of the *Gazette* enabled Stead to advocate for a number of causes, including women’s suffrage and his era’s antiwar movement. Yellow journalism was eventually seen as negative by the public when journalists began to compete with each other at being more sensational and more graphic—again, within the limitations of the era, in which “bad language” was not permitted no matter what.

Sensational reporting sold newspapers, but yellow journalism could also have serious consequences. In an era before the concept of objective reporting had been enshrined in the journalist’s vocabulary, many newspapers were unashamedly partisan. This could be a mixed blessing. In Hungary, for example, there was revolution in the air in 1848, as many Hungarians wanted independence from Austria. It was the

press that led the charge, thanks in large part to Lajos Kossuth, a lawyer whose views were considered radical by those in power. A fiery orator and writer, Kossuth used his position as editor-in-chief of the underground *Pesti Hirlap* (Newspaper from Pest) to promote nationalism and lead the drive for independence. While encouraging nationalism had a positive result in this case, there were other occasions when stirring up nationalistic fervor did more harm than good. The Spanish-American war in 1898 was largely attributed to newspaper owner William Randolph Hearst, who encouraged his reporters to inflame the U.S. public to support a war that most modern historians agree need never have been fought.

Telegraphy and Wire Services

The mid-to-late 1800s saw further expansion of journalism throughout the world. Technology was partly responsible: Steam driven locomotives now carried people to other cities more quickly, which was good news for reporters trying to cover an assignment. Better news was the invention of the telegraph, which made communicating from distant points infinitely faster. In both Europe and North America, new companies were founded to serve as resources for gathering news. The first news agency was founded in 1832 by Charles-Louis Havas; named Agence Havas, it originally translated the newspapers from foreign countries but by 1835 expanded to cover events around the globe. The government continually monitored it, but Agence Havas became a reliable resource for French-language newspapers. It survives to this day under the name of Agence France Presse. In May 1848 the Associated Press (AP) opened in New York. Founded by David Hale and James Gordon Bennett, it offered its U.S.-affiliated newspapers access to news dispatches from all over North America. In 1858 AP was able to receive dispatches from Europe for the first time, via transoceanic cable.

As use of the telegraph expanded, it became possible for the newspapers to receive and disseminate news on the same day, even from distant colonial outposts. This contributed to the impact journalism

had on a society that increasingly sought more information about world events. In Europe, in October 1851, a German immigrant working in London, Paul Julius von Reuter, began sending stock market quotations between London and Paris via cable. Prior to telegraphy, he had used the so-called pigeon post, sending the information via carrier pigeons. His new company, Reuters, quickly expanded, offering news-gathering services similar to those of the Associated Press. Members of the British press were among his first customers, but soon Reuters had affiliates throughout Europe. In 1865, Reuters was the first European news service to have the story that President Lincoln had been assassinated. Other European countries also established their own news-gathering organizations, often because of demands from businesses for global information that might affect them. Outside of Europe, the new technology was slow to arrive, so newspapers such as Australia's *Sydney Herald* still relied on news from ships until transoceanic cables were successfully laid and telegraph connections were established in major Australian cities, between 1858 and the mid-1870s.

A lack of modern telegraphy was also a problem in China. The Qing government appeared not to see the need for telegraph cable until it fought a war with Russia in the 1870s. Lack of speedy communication hampered treaty negotiations and led to several unfavorable treaties. The public was outraged, and this provided the impetus to begin expansion: from 1884 to 1899, 27,500 kilometers of cable was laid. The encroachment of other countries on China's sovereignty and territory led to a feeling of nationalism that manifested itself in the establishment of many newspapers and magazines from the 1860s through the 1880s. In the rest of the world, certain Latin American countries laid down telegraph lines in the 1850s, as did the Ottoman Empire, and lines were laid down in European colonies as well.

Radio and Television

The 1900s brought yet another dramatic change in journalism, as a result of another technological

The popular *Radio News*—"the 100 % wireless magazine"—sold for 25 cents in 1923.

advance. The inventors Guglielmo Marconi and Nikola Tesla were both experimenting with wireless communication, or what would later be called radio. It is generally agreed upon that the first broadcast was an experiment done by a Canadian engineer, Reginald Fessenden, in Massachusetts, but the exact date is not certain and is in fact the subject of much debate: some sources say it was on Christmas Eve 1906, whereas others place it earlier.

Some of the earliest commercial radio stations worldwide were operated by corporations, with the hope of selling merchandise or radio equipment. In North America, one of the first stations was XWA (later CFCF) in Montreal, owned by the Marconi Wireless Telegraph Company; it went on the air in December 1919. Another early station, KDKA in Pittsburgh, Pennsylvania, was owned by Westinghouse, which manufactured electronic equipment, while another, 8MK (later WWJ) in Detroit, Michigan, was owned by a newspaper, the *Detroit News*. At least one early North American station—WIAE in

Vinton, Iowa—was owned in 1922 by a woman, Marie Zimmerman. Mexico got its first station in December 1923, when CYL took to the air, owned jointly by two businessmen, Raul and Luis Azcarraga, and the Mexico City newspaper *El Universal* (The Universal). Puerto Rico's first commercial station, WKAQ, went on the air from San Juan in 1922, started by Joaquin Agusty, who was well known for his work with amateur radio. And one of the first radio stations in Cuba was PWX, owned by the Cuban Telephone Company in Havana; American radio fans reported hearing its powerful signal in 1922.

News was broadcast at a few stations in 1921 and 1922, and live sporting events were also broadcast during that time. But the staple of American programming was music. At first, because many of the owners were from the upper class, they felt their duty was to educate and to offer "good" music (opera and classical, as opposed to jazz, which they felt was vulgar), but gradually the public demand for dance and popular music won out at most stations. Radio was unique because it was the first mass medium to bring people an event as it was happening, and it also provided the poor and people of color access to places from which they were often excluded. With radio, people could hear the greatest vocalists, learn from famous professors, or just enjoy the hit songs in the privacy of the home. Radio helped to create a common culture, as certain songs or certain performers became popular across the country.

Early radio broke down borders in other ways too. Signals carried great distances, and listeners competed to see who could receive stations from the farthest away. In 1921 Eunice Randall, the first women announcer in Massachusetts, told a newspaper that she had received fan mail from people who heard her in London. Radio magazines such as *Radio News* began printing lists of stations from foreign countries, so that listeners could write down the ones they heard. And it was not just in North America that radio changed people's lives. *Radio News* reported in September 1925 how broadcasting was affecting the peasants in an impoverished Russian village. A radio and loudspeakers had been set up in a public listening

room so that people could gather and hear the news of the world; crowds eagerly awaited these broadcasts so they could find out what was happening outside the confines of their village. Meanwhile, the government had just begun permitting private ownership of radio sets in Moscow, and already over 50,000 receivers were in use. By the mid-1920s, many European cities were hosting radio expositions at which the public could meet radio broadcasters and see the newest radio receiving equipment.

By late 1926 the United States' first national network was on the air—the National Broadcasting Company, or NBC. It was able to offer its affiliates excellent programs with famous performers because the network was entirely supported by advertisers, who often chose the talent and decided what got on the air—a prerogative that resulted in women being relegated to stereotypic roles and minorities seldom being hired at all. By the end of the 1920s, few of the small entrepreneurs who had put the first stations on the air were able to afford to operate a radio station.

In many countries it was the government that operated the stations, which were supported by a receiver fee that listeners had to pay in order to own a radio receiving set. Great Britain was one such country. The British Broadcasting Company was founded in 1922, and the first station, 2LO, went on the air in November of that year. Right from the beginning, government interests tried to limit how much news could be broadcast, fearing that radio could influence the public's political views; newspapers also lobbied the government to restrict radio from doing news at all, since print journalists saw radio as competition.

As in Britain, in France, Denmark, and Germany the government quickly established control of broadcasting in the early 1920s. In at least one place, radio broadcasting was entirely controlled by the Catholic Church: Vatican City's first station was built in late 1930; the station would enable the pope spread his message worldwide.

In Argentina, a commercial station, Radio Argentina, was licensed in November 1923, and a high

powered station, LPZ in Buenos Aires, was on the air in 1924. Argentina was also an excellent market for American-made radio receivers. In Peru, as early as July 1921, a government-run shortwave station in Lima was put on the air at the request of President Augusto Leguia; it mainly broadcast weather reports and other information useful to the military and the police. The first commercial station in Peru was probably OAX in Lima, which went on the air in June 1925, broadcasting entertainment and educational programming. Many stations in Latin America were run by private companies, and although they were sometimes subjected to government censorship, in general, they were free to broadcast.

Radio broadcasting came slowly to Asia. In fact, there were fewer than thirty stations in all of Asia in 1927, whereas in North America, there were hundreds. In China, American and British businessmen seem to have set up the earliest radio stations; one of the first was in Shanghai in 1922. But the government did not allow radio broadcasting to become widespread; by 1931 there were only eighteen stations operating in the entire country. A national radio service, operated by the Communist party, did not begin until 1940. In Hong Kong, then a British colony, the government was equally cautious: amateur radio fans proposed a station as early as 1923, but it wasn't approved till 1928. Hong Kong only had that one station till the mid 1930s. In contrast, radio was welcomed in Japan, where the amateurs had been demanding it since the early 1920s. Tokyo's JOAK was the first commercial station, going on the air in March 1925 and quickly followed by stations in Osaka and Nagoya. Nippon Hoso Kyokai (the Japan Broadcasting Association, or NHK) was established as the official national broadcasting company of Japan in 1926. Modeling itself after the BBC, it took control of the three stations on the air and continued to expand throughout the country.

During the 1930s, NHK was also involved with experiments in early television, as was the Soviet Union, which conducted experiments with television as early as 1931. There were TV broadcasts in the Netherlands in 1935, and Great Britain inaugurated its national

service in November 1936: the first British television broadcast featured a song called "Magic Rays of Light," which certainly expressed the amazement people who witnessed it must have felt. Even prior to the establishment of electronic television, Great Britain was home to very primitive mechanical stations that broadcast sporadically in the late 1920s. A Scottish-born inventor, John Logie Baird, is regarded as the father of mechanical television in Great Britain, and he received considerable publicity despite the poor quality of the picture his system produced. In the United States, the inventor Charles Francis Jenkins was the father of mechanical television, and he too supervised some stations in the late 1920s. But it was the development of a far superior technology, electronic television (credited in the United States sometimes to an independent West-Coast inventor named Philo Farnsworth and sometimes to a corporate inventor who worked for RCA, Vladimir Zworykin), that eventually led to the United States' successful television industry.

Colonialism played a major role in the history of international broadcasting. Colonial governments set up radio stations (and later TV stations) and controlled their content, as they had with newspapers. Even stations that were set up as noncommercial were operated by and often benefited corporate interests. The British Marconi Company, which wanted to sell receiving sets, attempted to open stations in Bombay (Mumbai) and Calcutta, India, as early as 1922. An amateur organization in India, the Radio Club of Bombay, did some programming beginning in 1923, but the first commercial stations did not begin till 1927. When it became evident that World War II was on the horizon, interest grew in expanding the radio broadcasts to give the public more news and entertainment during difficult times. But a national service (All India Radio) did not flourish till India achieved independence in 1947. And in Central America, the United Fruit Company had great influence on what was broadcast, making sure news reports were favorable and nobody challenged the company's control over the banana industry. Even under colonial administration, nationalism could lead to conflicts about

what should or should not be broadcast. In the British mandate of Palestine (present-day Israel), the British set up the Palestine Broadcasting Service in March 1936. Although BBC announcers trained the staff and programming was offered in Hebrew, Arabic, and English, neither Jews nor Arabs were happy with what was on the air. The same problem occurred in a number of other ethnically divided countries, where ethnic tensions played out in a struggle for control of the country's radio stations.

The Media Divide: Comparing Rich and Poor Nations

One organization that has been monitoring trends in international media is UNESCO (United Nations Educational, Scientific and Cultural Organization), which held its first international conference on communication policies in 1974 in Costa Rica. At that conference, a declaration was issued, urging that in crafting their communications policies, nations should take into account national realities but also the promotion of free expression of thought and respect for individual and social rights. In subsequent conferences, declarations were made about the necessity of protecting the rights of journalists and giving all people—not just the rich and the powerful—access to information. An international commission, with members from fifteen countries, convened in 1977 and began issuing reports on the state of the media. Their first report, *Many Voices, One World*, was issued in 1980 and was the first in-depth study of the media in both rich and poor countries. It identified disparities in access to media: in Africa, for example, 1976 statistics showed that only 3 percent of the population owned a radio, which was troubling because “[r]adio is of vital importance to developing countries because of [the] low penetration of newspapers into rural areas and . . . because of illiteracy on a mass scale” (MacBride 1980, 122–127). The commission also identified the countries that had kept pace with advances in communication technology—Japan, for example, composed only 5 percent of Asia's population yet it had “66 percent of the press circulation,

46 percent of the radio receivers, 63 percent of the television sets and 89 percent of the telephones” (MacBride 1980, 122–127), according to 1979 research. The study found that while India had 835 different newspapers, eight African countries had no daily newspaper at all, while others had only a weekly or a biweekly that was not distributed outside of main centers of population. Even in developed countries that had radio or newspapers or television, most of the coverage was about what was going on in the biggest cities. And although media consolidation was not the issue in 1980 that it is today, there was already evidence that a handful of elites controlled the communication in many countries. As the commission noted, issuing a declaration about press freedom or equal access did not mean that those goals would be reached or that governments would cooperate.

Since that first UNESCO report, more countries now have technology, and a growing number have Internet newspapers. Perhaps the first in Africa was the *Mail and Guardian Online*, started in South Africa in 1994. Saudi Arabia began an English-language service, *ArabNews Online*, around 1998; it was an offshoot of the English-language daily newspaper, *Arab News*, which had been established in 1975. What the average Saudi has access to remains limited. The ability to communicate in English was desirable primarily for the elite, who were taught the language in private schools so they could engage in commerce with the West. The average person mainly went to religious schools, but the educated elite then and now were taught English. The fact that the on-line *Arab News* publishes in English provides it with the ability to reach out to educated Saudi expatriates as well as to American and British diplomats. The ruling class and the clerics in Saudi Arabia at first opposed modernizations such as radio, which by all accounts did not start till the 1930s—the clerics only accepted radio when King Abd al Aziz tied its use to the religious purpose of airing scriptural lessons and teaching illiterate people more about their religion. For those who have access to it, the Internet can provide a means of resisting tyranny. Women human rights activists in Afghanistan founded RAWA (Revolutionary

Association of the Women of Afghanistan) and made use of online communication and a website to mobilize supporters worldwide during the repressive Taliban regime of the 1990s. Even in countries in which the average citizen lacks access to the Internet, exiles are often able to use it to spread the word of what is happening in their country. It has become harder for repressive regimes to control information or prevent it from being disseminated, but it can still be done: in Burma (Myanmar), the autocratic government has been successful in keeping dissenting voices from being heard, and in Iran, when protesters questioned the legitimacy of the elections in 2009, the government banned Western TV and radio reporters, and shut down most internet sites, while limiting access to social networking sites.

Mass Media and Violence

Being a journalist can be a dangerous occupation. The International Press Institute in Vienna stated that in 2003, sixty-four journalists were killed; nineteen of them died in Iraq and nine in Columbia. Also in 2003, the Committee to Protect Journalists named Iraq, Cuba, Zimbabwe, Turkmenistan, and Bangladesh as the most unsafe places for journalists. According to the CPJ, while Iraq was a war zone and any reporting from a war zone can be dangerous, the other countries had repressive governments that lock up and in some cases torture journalists whose opinions they do not like. By 2008, conditions for journalists remained unchanged—once again, sixty-four journalists were killed, with Iraq and Pakistan having the most deaths. In some countries, journalists have just disappeared, usually after reporting on a story the government disliked, or uncovering the activities of organized crime. That was the case in Mexico in 2007 when investigative reporter Rodolfo Rincón Taracena vanished after reporting on local drug trafficking. Reporters covering drug-related crime in Latin America were also frequently in danger: in Peru in 2006, forty journalists were attacked, and in Columbia, three were killed and many others had to go into hiding. In Haiti, where news is still spread by *teledjol* (word

of mouth) and illiteracy is rampant, radio remains the most important mass medium: according to some reports, about 92 percent of Haitians own a radio and the country has over three hundred stations. For that reason, the government has sometimes tried to suppress the country's radio stations: Jean Dominique, director of a popular language station, denounced the government and accused it of rigging the elections; he was gunned down in April 2000. There are reports that Haitian radio stations have gradually gained more freedom since then, although journalists have admitted to practicing self-censorship. In some countries, the media have also been used by those in power to incite the population to violence. One especially egregious example of this occurred during the Rwandan genocide of 1994, when a government radio station, RTML, encouraged Hutus to murder members of the Tutsi minority. Radio broadcasts referred to Tutsis as “vermin” and “cockroaches” and repeatedly demonized them. Transcripts show that some announcers even pointed out where Tutsis were living and encouraged Hutus to kill them.

Looking to the Future

In the Muslim world, the arrival of the cable news television station Al-Jazeera (Arabic for The Peninsula) in 1996 has been dramatic. Critics have called the Qatar-based station sensationalistic and biased and have accused it of stirring up anti-Jewish and anti-American sentiments in the Arab world. But many Muslims counter that it is the first network to report from a pro-Arab point of view. Unlike CNN or Fox, American cable networks with a decidedly American and Western viewpoint, Al-Jazeera has called American forces in Iraq “occupiers” and referred to those who were fighting against the Americans not as “militants” but rather as “resistance fighters” or “martyrs.” Al-Jazeera has grown in size and influence in the years since its founding; since 2003, it has competition from Dubai-based Al-Arabiya, which also offers news from a pro-Arab point of view, but is perceived by Western observers to be more moderate in its coverage. It will be interesting

to see the direction these stations take in the years to come. Cable television has become a growing presence in a growing number of Arab countries in the first decade of the twenty-first century. And while many Arab stations, both radio and TV, are religious in nature, there are also stations that broadcast a wider variety of programming, including popular movies. One example is ART (the Arab Radio and Television Network), which was founded in Saudi Arabia back in 1993.

While globalization has affected how business is done worldwide, it has also affected the mass media. In the United States, deregulation of broadcast media began in the 1980s under President Ronald Reagan, culminating with the 1996 Telecommunications Act, signed by President Bill Clinton. The Telecom Act lifted restrictions on how many stations could be owned by one company. Rather than encouraging competition as proponents claimed it would, the end result was consolidation of power into the hands of a few giant media conglomerates, several of which (Clear Channel Communications, which at one point owned over a thousand radio stations and a major concert promotion company; and News Corporation, owner of cable channel Fox News as well as numerous newspapers and magazines) had ties to conservative politics and the Republican party. In the buildup to the invasion of Iraq, critics accused these conglomerates of stifling dissenting views and only broadcasting coverage in favor of going to war.

Similar media consolidation occurred in Canada, where in the period from 1985 to 2000, consolidation occurred in dramatic fashion. By 2000, 68 percent of all television stations were controlled by five giant companies, and one conglomerate, the Hollinger Corporation, soon owned or had a financial interest in 80 percent of Canada's daily newspapers. Eventually, financial problems caused Hollinger to sell off many of those newspapers, but they were bought up by another conglomerate, CanWest.

Media consolidation is also a fact of life in parts of Europe. In England, there has been increasing pressure on the government to relax media ownership laws. One major proponent of removing the

limitations is Rupert Murdoch; in addition to owning the American conglomerate News Corporation, he also owns several British newspapers (including the *Times of London* and a tabloid, the *Sun*) and a satellite programming service called BSkyB (British Sky Broadcasting), as well as media properties in Australia. Murdoch has been accused by his critics of censoring news stories that are contrary to his political views. Meanwhile, in Italy, the controversial prime minister Silvio Berlusconi, also had ties to media ownership; companies owned by his family dominate Italian television, and he has attempted to pass legislation that would permit his conglomerate to expand its ownership of newspapers. He has also used his influence to make sure the state-run broadcaster RAI is controlled by a board of directors that is favorable to him. Critics have accused him of using his wealth to manipulate media coverage, in order to avoid having his questionable financial dealings scrutinized.

In other countries too, a similar trend towards consolidation can be seen. Where media were at one time comprised of government-run monopolies, the new concern is that commercial media conglomerates are stifling opposing voices in the same way that the state-run media once did.

There are some hopeful media signs in countries where repression used to be a part of life. After the breakup of the Soviet Union in 1991, an era of comparative freedom of the press began in Russia. While the press was reined in somewhat by the government of President Vladimir Putin, who was in office (2000–2008), it is still far more free than it was in the era of Soviet rule. But being a journalist in Russia can still be dangerous: the Committee to Protect Journalists notes that when journalists are murdered there, the killers are seldom if ever brought to justice. The news is more positive for journalists in Haiti. Radio stations that were shut down by the government have quietly reopened since the ouster of President Jean-Bertrand Aristide in 2004. And in Rwanda a new radio service promotes not hatred but friendship and entertainment. Similar to pop music radio stations in the United States, Rwanda Radio in Kigali has opportunities for

listeners to call in, a morning talk show, modern pop music, and even a children's trivia contest in which the winners get to talk on the air. Young and articulate announcers offer listeners helpful information about health, and they also teach tolerance. Where radio had once been part of the problem, it is now trying to be part of the healing process.

Mathematics

The twenty-first-century approach to the history of mathematics looks beyond the once-traditional Eurocentric views that credited the Greeks for the most advanced developments; it now embraces a global view of mathematical accomplishment through the ages and cross-cultural exchanges in the field.

The traditional history of mathematics took shape at the turn of the twentieth century, reflecting the European influence of that era. According to this traditional history the first mathematics worthy of the name arose in ancient Greece and led directly, but for the Dark Ages, toward the modern mathematics of Western universities today. Since the mid-twentieth century historians of mathematics have broadened their subject's horizons. New historical evidence and changing attitudes toward other cultures have made this history of mathematics more complex and more global. Equally important have been changes in what is considered mathematics. The key to the study of a truly global history of mathematics has been flexibility in the definition of mathematics itself. The term *ethnomathematics* refers to the mathematical practices of a particular society and includes mathematical processes beyond the narrow academic sense, in recreation, art, numeration, and other fields. A more conceptually inclusive definition of *mathematics* has led directly to a more geographically inclusive history of mathematics. We can see the greatest diversity in mathematical practices by comparing counting systems around the world, such as the Incan *quipu*, a knot-tying system for recording numbers.

Toward a Hellenistic Synthesis

Hundreds of well-preserved clay tablets (most dating from c. 1700 BCE) disclose the sexagesimal (base sixty) numeration system of ancient Mesopotamia, a system sufficient for the development of an ancient algebra. The sources for early Egyptian mathematics are far fewer. The earliest, the Ahmes Papyrus, is a copy of an earlier version from about 1900 BCE. In addition to developing an arithmetic distinctive for its reliance on unit fractions ($\frac{1}{4}$, $\frac{1}{3}$, $\frac{1}{2}$, etc.), Egyptians elaborated a practical computational geometry with methods for calculating the volume of a truncated pyramid and approximating the area of a circle.

Only recently have historians begun favorably to reevaluate the achievements of Mesopotamia and Egypt because none of their earliest mathematics adopted the deductive and theoretical approach of the Greeks—an approach that has become enshrined in modern definitions of mathematics. The Greeks themselves, however, explicitly acknowledged their debt to the Egyptians. Moreover, after the conquests of Alexander of Macedon (Alexander the Great, 356–323 BCE) spread Greek thought throughout southwestern Eurasia, a shared Hellenistic culture united the mathematicians of the new world order, and the great Greek geometer Euclid (early third century BCE) taught in the Egyptian capital Alexandria. The Hellenistic world witnessed an extraordinary synthesis of Greek deductive geometry with the algebraic and empirical mathematics of neighboring peoples.

Indian Mathematics

The earliest Indian mathematics was expressly religious in purpose. The geometry developed in the *Sulbasutras* (technical appendices to Hindu sacred writings, the Vedas, c. 3000 BCE) adopted sophisticated techniques, including the Pythagorean theorem, for the proper orientation and construction of effective sacrificial altars. A hymn from the *Atharavaveda* (the name translates to Sacred Knowledge of Magical Forms) describes a complex design of overlapping triangles for meditation.

Possibly during the Vedic period, and certainly by the seventh century CE (perhaps inspired by the counting boards brought by Chinese travelers), a decimal place-value system arose that in principle is like our own: distinct numerals represented the numbers 0 through 9, and each instance of a numeral would be associated with a decimal scale based on its position in the number. (The first dated inscription of such a system, however, comes from Cambodia in 683.) Most early mathematical knowledge was preserved orally in verse.

The decline in Vedic sacrifices after about 500 BCE shifted the focus of Indian mathematics. The developing Buddhist and Jaina traditions involved large numbers. (The religion of Jainism, originating in sixth-century-BCE India, taught liberation of the soul.) The collection of Buddhist texts *Samyutta Nikāya* (The Grouped Discourses), for example, defines a *kalpa* as a unit of time longer than that needed to erode a rock of one cubic mile by wiping it with silk once a century. The Jainas worked with series and permutations, and they theorized that not all infinite numbers are equal, an insight that would elude Western mathematics until the nineteenth century. Only with the practical, commercial algebraic examples of the Bakhshali manuscript, composed in the first centuries CE, did Indian mathematics lose its primarily religious applications.

Later Indian mathematics would achieve breakthroughs in indeterminate equations, as well as in trigonometry and its application to astronomy. Algebraic work used Sanskrit letters abbreviating the

names of colors to stand for unknown qualities, like the modern x and y , and until the modern period the use of letters of the alphabet to represent numerals would reinforce the poetry of Indian mathematics. The research on power series (series—sum of a sequence of terms—in which the terms follow a certain pattern and are infinite) for pi and trigonometric functions by fifteenth- and sixteenth-century mathematicians in Kerala in India anticipated many of the results achieved by the English physicist and mathematician Isaac Newton and the German philosopher and mathematician G. W. Leibniz—independently, or perhaps through the Portuguese—in the seventeenth century. Proofs and derivations of formulas were quite rare throughout the Indian mathematical tradition.

Chinese Mathematics

The first existing numerals appeared on Chinese Shang dynasty (1766–1045 BCE) tortoise shells used for divination, with symbols to indicate 1 through 10, 20s, 100s, and 1000s. The oldest treatise is the *Zhoubi Suanjing* (The Arithmetical Classic of the Gnomon and the Circular Paths of Heaven) (500–200 BCE), an archaic astronomy text that contains a demonstration of the Pythagorean theorem. In China counting rods were used for elementary arithmetical operations at least by the Qin dynasty (221–206 BCE). China also boasts the earliest known magic squares, which are matrixes of numbers in which every row, column, and major diagonal produces the same sum. Interest in magic squares as protective talismans encouraged their spread to Mongolia and Tibet, although they were limited in size to three by three until Yang Hui's work in the thirteenth century.

The principal classic source was the *Jiuzhang Suanshu* (Nine Chapters of the Mathematical Art), composed during the Han dynasty (206 BCE–220 CE). Eminently practical, its nine chapters included 246 problems treating land surveying, proportions of millet and rice, volumes of three-dimensional solids, and tax assessment. Some results were precocious,

Let no one enter who does not know geometry. • **Inscription on Plato's door** (c. 427–c. 347 BCE)

and the approaches to simultaneous linear equations closely approximated the methods later developed by the German mathematician and astronomer C. F. Gauss (1777–1855). The preeminence of this work sparked during later centuries numerous commentaries elucidating the often obscure explanations. If for some people the commentaries inhibited creative work, other people used the commentaries to introduce original research.

Although geometry largely stagnated at the level of the *Jiuzhang Suanshu*, Chinese scholars made important advances in algebra and arithmetic. During the fifth century Zu Chongzhi calculated pi to seven decimal places, an achievement first surpassed by the Indian mathematician Madhava around 1400. In 1247 the “0” sign for zero first appeared, and later in the century Guo Shoujing became the first Chinese mathematician to tackle spherical trigonometry. Both developments may have occurred under Arab or Indian influence. Zhu Shijie (1280–1303) presented the French scientist and philosopher Blaise Pascal's triangle and algebraic methods for solving simultaneous equations and equations of high degree. Only in the eighteenth century would European algebra catch up with Chinese.

Islamic Mathematics

The Islamic 'Abbasid caliphate (the office or dominion of a Muslim spiritual leader) (750–1258 CE) sponsored missions to gather astronomical texts (and scholars) from a variety of cultures. Islamic mathematics had two major sets of sources. The first consisted of Persian and Indian sources that featured prominently astronomical tables and an algebraic approach. The second set of sources was Hellenistic, sometimes transmitted through Syrian intermediaries and translations. In their deductive and abstract approach these works in the second, Hellenistic set of sources betray their Greek origins.

The most famous developer of the first Islamic mathematical tradition was al-Khwarizmi (c. 780–c. 850). His treatise *Hisab al-jabr w'al-muqabala* (Calculation by Completion and Balancing) gives us the

word *algebra*, and his *Algorithmi* introduced the word *algorithm* and the Indian positional number system—which had probably first moved out of India with Nestorian (relating to a church separating from Byzantine Christianity after 431) Christians, who found it useful in calculating the date of Easter. In the second mathematical tradition Thabit ibn Qurra (c. 836–901) proved the Pythagorean theorem, attempted a proof of Euclid's parallel postulate, and made discoveries in mensuration (geometry applied to the computation of lengths, areas, or volumes from given dimensions or angles) and spherical trigonometry.

In addition to preserving these earlier texts in Arabic translation and making further progress within these two traditions, several mathematicians of the Islamic world worked toward a synthesis of Greek deductive geometry and Indian algebra. The fusion of the two streams is best represented by the application of geometry to algebra evident in the geometric solution to quadratic and cubic equations pursued by al-Khwarizmi and the Persian poet and mathematician Omar Khayyam (c. 1040–1123). In addition to pursuing further work on the parallel postulate, Omar Khayyam pursued calendar reform and a theory of proportions useful for the inheritance problems of Islamic law. Jemshid Al-Kashi (1380–1429) relied on a near-circular polygon of 805,306,368 sides to approximate pi to sixteen decimal places. Arab mathematicians enhanced the Indian number system by introducing in the tenth century a small vertical line over the units place to serve the same purpose as the modern decimal point. Nasir al-Din al-Tusi (1201–1274) anticipated the mathematical improvements of the model of the cosmos developed by the Polish astronomer Nicolaus Copernicus (1473–1543).

Toward a European Synthesis

Indian numbers reached Europe by the tenth century, were popularized by the *Liber abaci* (Book of Calculation) of the Italian mathematician Leonardo Fibonacci (1170–1250), and slowly overcame prohibitions by various governments (concerned that the system

The Italian mathematician Leonardo Fibonacci popularized the Hindu-Arabic number system in early-thirteenth-century Europe.

facilitated fraud) that lasted until King Charles XII of Sweden (1682–1718). The Hindu-Arabic system of our modern numbers attracted merchants with its usefulness in calculations—and attracted swindlers with its easily altered numbers. In Europe resistance to mathematics was not limited to the new number system. The German religious reformer Martin Luther considered mathematics hostile to theology, and the establishment of the Savilian chair in geometry at Oxford University in England prompted concerned parents to withdraw their sons, lest they be exposed to diabolical mathematics.

During the early modern period, as Europeans increasingly exerted influence across the globe, they also began to dominate a mathematical tradition that itself was absorbing compatible elements from other cultures. The dominance of a single stream of mathematics, perhaps fed by many cultural tributaries, is characteristic of modern mathematics.

Europe's mathematical exchange with China illustrates how global connections created this single

stream. In 1607 the Jesuit Matteo Ricci and the Christian convert Xu Guangxi (1562–1633) translated Euclid's *Elements* into Chinese. Although Euclid's deductions contrasted sharply with the inductive approach of the *Jiuzhang Suanshu*, the translation proved highly influential in subsequent Chinese mathematics. Many of the technical geometric terms coined by Xu remain in use today. Other cross-cultural mathematical connections are less certain. Mathematics from Kerala may have traveled to China, and the *Elements* may have already been introduced by Arabs. In the other direction, the Jesuits possibly reported some advanced Chinese algebra back to Italy.

Under Chinese imperial sponsorship the text *Shu Li Jing Yun* (Collected Basic Principles of Mathematics, 1723) marked the end of the integration of Western techniques into Chinese mathematics. During the next emperor's reign a new closed-door policy restricted access to Western research. Some Chinese worked on critical editions of ancient mathematical texts, while others conducted research in isolation from the West. In 1859 Dai Xu (1805–1860) proved the binomial theorem independently of Newton, whose own 1676 proof had not yet reached China.

Outside the mainstream of Western mathematics stood the Indian prodigy Srinivasa Ramanujan (1887–1920) and his discoveries in the theory of numbers. Although his genius had no contemporary rival, his knowledge of mathematics was limited. Some of his theorems (for example, on the theory of prime numbers) have thus been described as brilliant but wrong. His cavalier attitude toward proof was once attributed to this background, although it in fact fits the Indian pedagogical tradition of leaving demonstration and commentary to students.

The twentieth century has brought a remarkable international tradition of mathematical scholarship often transcending geopolitical divisions. In 1897, 208 mathematicians met in Zurich, Switzerland, as the first International Congress of Mathematics (ICM). Representing sixteen countries, they included twelve from Russia, seven from the United States, and four women. The Cambridge ICM of 1912 counted 82 non-Europeans among its 574 participants. Founded

just after World War I, the International Mathematical Union (IMU) excluded the defeated Germany until the IMU adopted a policy of principled neutrality in the 1920s—a policy that would endure despite the challenges of World War II and the Cold War. The mainstream did divide somewhat as Communist and Western mathematicians developed results in parallel, at a lag in either direction, often with different methods. The Commission on Development and Exchange (known before 1978 as the “Commission for Exchange of Mathematicians”) was established in 1959 to facilitate the development of mathematics beyond industrialized countries. The African Mathematical Union formed in 1976, although the exodus of mathematicians from underdeveloped nations to Western research institutes continues to concern some observers.

Outlook

As historians discover new sources and question old attitudes, the global history of mathematics will continue to expand. The nature of mathematics perhaps makes it more likely to move across cultural boundaries intact, and serious inquiry into the global dissemination of mathematical ideas has only begun. Unfortunately, because so much mathematics has evolved in traditions that do not value the citation of sources, exact lines of transmission will be hard to re-create.

Matriarchy and Patriarchy

Patriarchy (literally defined as “rule by the fathers”) and its opposite, *matriarchy*, are terms used to account for the historical development of systematic societal relationships between men and women, especially in feminist and gender studies regarding the male dominance and oppression of women and children.

Patriarchy has emerged as an important explanatory concept in contemporary feminist theorizing and research to account for the development and maintenance of systematic gender inequality through male dominance that resulted in the oppression of women and children. Like other widely used terms in feminist research and theory, such as *feminism* and *gender*, there are several views of patriarchy and its usefulness as an explanatory concept for understanding women’s oppression.

Matriarchy, on the other hand, has not received as widely accepted a response as an explanatory concept in feminist theorizing about the historical development of social relations between men and women. Of particular concern here is the debate concerning the existence of matriarchal societies in the emergence of human societies. Specifically, this debate centers on the notion that a pre-matriarchy existed prior to the emergence of patriarchal societies in the foraging and Neolithic eras. This debate has emerged in feminist religious studies, particularly in relation to finding the historical antecedents of contemporary feminist goddess spirituality and documenting what might be called a sacred history for the movement. Also relevant here are the recent attempts of U.S. historians to explain the unequal economic and political position

of African Americans as a result of the myth of the “black matriarch.”

Through the discussion of matriarchy and patriarchy as explanatory concepts, this article will highlight the ways in which these concepts constitute a form of discourse about power in social and relational terms as well as in institutionalized contexts. It will underscore the shifting and changing explanatory modes of the terms *matriarchy* and patriarchy while providing an overview of the associated meanings of these concepts.

What is Patriarchy?

In its simplest terms, the word patriarchy draws its roots from the Greek (*pater* = father and *arch* = rule; literally, “rule of the fathers”). (Patriarchy can also be used in a generic sense to mean rule by men, and sometimes more narrowly to mean a society where a father rules his wife, children—usually not adult—and any employees in the household.) But the concept of patriarchy encompasses more than the organization and social relations of power within families and households. It also addresses the systemic discriminatory practices of unequal power that institutionalize male dominance in social, cultural, economic, and political life with the attendant ideological justification in religious and legal frameworks that serve to both institutionalize and naturalize this power dynamic.

The theoretical studies of the sociologist Bonnie Fox allow for four major perspectives on patriarchy as an explanatory principle in feminist theorizing and research, including their limitations and insights. These include (1) patriarchy as “collective male dominance”;

Franz Xavier, *Penthesilea, Queen of the Amazons* (late 18th c.). Wood engraving. Today's feminist "warriors" struggle to end gender inequality and the oppression of women.

(2) patriarchy as a "self-contained system"; (3) patriarchy as a system of reproduction; and (4) patriarchy as a "sex/gender system."

In the first instance, "patriarchy as collective male dominance," the perspective defines patriarchy in universal terms. The lack of attention to causality and the resultant ahistoricism and essentialism of this perspective renders it problematic, since it asserts that all men, at all times, have sought out dominance over women. For Fox, attention to causality through a focus on social relations is crucial.

The second perspective, "patriarchy as a system," addresses the problem of causality by locating the material basis of patriarchy in the domestic, household relations between men and women. From this perspective, the basis of patriarchy is the economic dependence of women on men and the control of their sexuality through heterosexual marriage. What the theorist Heidi Hartmann calls a sexual division of labor, which allows men to benefit from women's domestic labor, is the basis of men's dominance over women. The critique of this perspective is the problem of motive: from this perspective, male agency

expressed as the desire to dominate women is seen as the motivation for the establishment of patriarchy.

In the third approach, "patriarchy as a system of reproduction," the problem of motive is located in the reproduction of human beings. Patriarchy, from this perspective, is rooted in the control and management of human reproduction in the context of capitalism. The focus here is on the control of women's sexuality and fertility as capitalism and patriarchy are seen as "dual systems."

From the fourth perspective, "patriarchy as a sex/gender system," the emphasis is on the production of gendered and sexed individuals in traditionally defined terms. From this perspective, patriarchy is intimately concerned with both the production of "gendered subjectivity"—the production of "men" and "women" as culturally defined and the production of "gendered subjectivity itself"—that is, the production of two distinct sexes and genders. Thus, patriarchy is a "system involving the production of two distinct sexes and genders that are disposed to mutual sensual attraction and dependence in terms of labour, ensures biological reproduction, and a functioning economic unit consisting of a man and a woman" (Fox 2001, 325). The sex/gender system is a basic part of the way in which human societies have developed and is historically variable.

The synthesis that Fox highlights is that patriarchy from the perspective of being a sex/gender system is involved in both the production and the reproduction of people and the social organization of societies in a fundamental fashion. In situating patriarchy as a sex/gender system involved with the production of gendered subjectivity, it is important to look at three interrelated areas: the production of subsistence, the production of people, and the production of sexuality as integral at the level of both social structure and the individual, including both interpersonal relations and subjectivity.

Resisting Patriarchy

Since patriarchy is a fundamental aspect of how human beings' subjectivity and social organization

is organized and given its inherent inequality, how can it be resisted? On what basis can the struggle to end gender inequality and women's oppression be waged? The answer to this question has occupied feminist theorists and activists across a variety of political strata and involved both the transformation of interpersonal relations and the wider social structure. One idea that has received particular attention is that dismantling patriarchy lies in challenging the normative definitions of subjectivity in the production of masculinities and femininities under capitalist production.

Thus, lesbianism, for instance, is seen as a political resistance to patriarchy by the theorist Adrienne Rich precisely because it challenges the sex/gender system's reproduction by removing women from their historical subordinate role in heterosexual marriage and sexuality. From this perspective, "compulsory heterosexuality" is the fundamental means through which male dominance is perpetuated. Compulsory heterosexuality points to a situation in which women are compelled through cultural norms imposed by men to enter into the system of heterosexual sex and marriage that ultimately does not benefit them and maintains their subordination. Lesbianism, therefore constitutes a form of resistance to heterosexuality. But as compelling and influential as Rich's thesis is, the concept of compulsory heterosexuality was challenged on the grounds that the locus of women's oppression is not based in marriage or heterosexuality but rather in the supervaluation of masculinity and masculine desire over women's sexuality.

Challenging Patriarchy as an Explanatory Concept

One of the main challenges to patriarchy as an explanatory concept for all women's oppression emerged from the theorizing of black women and other women of color who criticized the essentialism and universalizing tendencies of an explanation that did not take into consideration the importance of race, color, and class as social relations of power. Their critique addressed the notion that all women's

Medieval depictions of biblical patriarchs and male dominance: Aaron's Rod; Moses Parting the Red Sea; Egyptians Drowned; and the Canticle of Moses.

experiences are based in gender oppression and argued for a consideration of the interrelated matrixes of power based on race, class, and gender. Women's lives were affected differently in different parts of the world during different historical time periods, depending on their relationship to race, class, and gender power relations.

From this perspective, white women married to men who owned enslaved Africans in the U.S. South and elsewhere in the slaveholding societies of the Americas did not experience gender oppression due to patriarchy in the same way that enslaved black women did. In fact, their gender, class, and race status in a society in which chattel slavery was intimately tied to hierarchies of race and color gave them privileges that distinguished them from enslaved black women. Thus, the histories of slavery, racism, and sexual exploitation experienced by black women

A little more matriarchy is what the world needs, and I know it. • **Dorothy Thompson (1893–1961)**

need to be addressed to understand black women's oppression. By assuming a singular feminine experience through the uncritical use of the concept of patriarchy and failing to consider women's divergent historical experiences, feminist analysis runs the risk of repeating the inequities based on race and class. The charge is that because the normative feminine experience is invariably layered by class- and race-based assumptions, white, middle-class Western women's experiences become central to feminist analysis and theorizing.

In the face of such theorizing, the concept of patriarchy continues to be used with attention to historicity. The theorist Elisabeth Schüssler Fiorenza, for example, defines patriarchy as a pyramid of interlocking dominations. She uses the term *kyriarchy* from the Greek *kyrios* (lord or master) to describe the patriarchal power that operates on the basis of interlocking systems of oppression based on gender, race, class, culture, and religion.

Matriarchy and Myth

While the use of the concept of patriarchy to explain women's oppression has gained currency in contemporary feminist theorizing, its opposite—matriarchy (literally, from the Greek, “rule of the mothers,” but understood more commonly as rule by women)—has not been as widely accepted, and some have doubted the past that it describes. A debate emerged within feminist religious studies circles concerning the reality of pre-patriarchal cultures in which women's lives and interests were celebrated. Evidence of this time in human history when the feminine principle was not devalued is directly related to the evidence of religious practices and imagery that celebrate the feminine principle in the form of a mother god (as opposed to the father god of patriarchal cultures).

The work of scholars such as Carol P. Christ, Merlin Stone, and Marija Gimbutas recast and reinterpreted the historical record. Christ, for example, challenged the historian Mircea Eliade's account of religious development as androcentric or male-centered and recast the role of women in the foraging

and Neolithic eras as vitally important. She used the notion of “woman the gatherer” to challenge the assertion that “man the hunter” was central to the social reproduction of human societies. But these reinterpretations have largely been dismissed as unfounded and wishful, based more on a desire to create a sacred history than on sound archaeological interpretations. In fact, the use of archaeological evidence to further contemporary feminist views of prehistory has been seriously questioned. From this vantage point, the complexities of hunter/gatherer societies are largely erased in favor of speculations about the role of women in these early societies. But it is difficult to sufficiently reconstruct foraging era or Neolithic social structure from archaeological evidence in order to draw accurate conclusions about the religious systems and symbols, and a reconstructed religious role may not actually represent the status of women or their social roles.

In fact, the assumption of a matriarchy based on the existence of matrilocality and matrilineality has been questioned. (Matrilocality refers to situations in which a husband lives with the wife's family on the wife's family's land. Matrilineal descent traces lineage through the mother's line.) Matrilocality and matrilineality, however, are distinct from matriarchy because their existence is not based on women's having political and social power over men. Finally, the overwhelming focus on the goddess, especially through the female body, life cycle, and reproduction potentiality, may produce a kind of essentialism about women's experiences that could, ironically, reinforce dominant patriarchal notions of femininity. But while these criticisms have been launched against the search for a history of the goddess in pre-patriarchal societies, they do not negate the importance of historical reinterpretation in creating a sacred history for feminist spirituality. Indeed, the recasting of history from this viewpoint serves a powerful ideological role in contemporary feminist spirituality.

One aspect of the matriarchy/patriarchy debate is the importance of female power and claims of matriarchal social order among many first peoples. Whether some of these societies were or are matriarchal, the

The dogma of woman's complete historical subjection to men must be rated as one of the most fantastic myths ever created by the human mind. • **Mary Ritter Beard (1876–1958)**

claim that women had much more power and authority in them, and the claim by some that they are now and then were matriarchal, are important aspects of their ethnic identity. Matriarchal or at least non-patriarchal social organization functions to distinguish these societies from the patriarchal societies that took over their territory.

In another instance of contemporary myth making, the concept of matriarchy was invoked to suggest that black women's emasculating dominance of black men was directly responsible for the social and economic inequities evident among black populations in 1960s America. In a 1965 study, Senator Daniel P. Moynihan suggested that a matriarchal black family structure was directly responsible for the inequities faced by black men and women. Black male patriarchal authority was seen as necessary for rectifying social and economic disparities with the wider society. In other words, rather than citing systemic inequality in all areas of social life, from slavery through the era of segregation known as Jim Crow, Moynihan placed the responsibility for the black community's disparity at the feet of black women. The political philosopher Angela Y. Davis critiqued this thesis as a continuation of a line of thinking that suggested the deterioration of black family life under slavery and its continuation into the post-slavery era. Davis noted that instead, black women's experiences under slavery, including acts of resistance and the protection of themselves and their families, created the legacy of a new womanhood for their descendants.

The Ongoing Debate

A review of perspectives on patriarchy shows that patriarchy produced a sex/gender system that led to gendered subjectivities. Matriarchy, on the other hand, is not as widely accepted as a way of understanding the development of relations between men and women and gendered subjectivities. The ongoing debate over the veracity and relevance of pre-patriarchal goddess-based societies shows that while the accuracy of such scholarship may have been questioned, it helped to create a sacred history for the contemporary feminist

spirituality movement. Second, the myth of the black matriarch as espoused by Moynihan's 1965 study may be seen as simply another instance in which the concept of matriarchy was used to reinforce long-standing racial stereotypes about black women as emasculators of black men, who inhibited the exercise of patriarchal power within black families. This particular construction of a black matriarchal family structure upheld patriarchy as normative in American society.

Both the Moynihan study and the reinterpretation of foraging era and Neolithic human societies to create a sacred story for feminist spirituality and to challenge male-dominant accounts of religious history point to the use of matriarchy and patriarchy as concepts that speak as much about interpretations of historical relations between men and women as they do about contemporary gender relations and the nature of theorizing and knowledge production. These concepts are clearly not neutral, and their use to address the development of gendered subjectivities and gender relations in human societies continues to be contested.

Mehmed II

(1432–1481)

OTTOMAN SULTAN

Mehmed II, the twice-reigning sultan of the Ottoman Empire in the mid-to-late fifteenth century, instituted new laws codes that served as the core of Ottoman legal system well into the seventeenth century. During his reign he accepted into his service talented men of various nationalities and religions.

Mehmed II reigned twice as sultan of the Ottoman Empire (1444–1446 and 1451–1481) and is often viewed as the ruler who transformed the Ottoman state into a true empire. Born the fourth son of Sultan Murad II, he first became sultan at age twelve when his father abdicated in 1444. Mehmed II's youth, however, prevented him from asserting his authority over some court factions; thus the state could not effectively deal with internal rebellion and foreign invasion.

As a result, Murad II returned from private life to assist in leading the Empire's armies and defeated an army of crusaders at Varna (a city on the Black Sea) in 1444. Murad II's presence raised questions as to whether Mehmed II was still sultan. An uprising by the Janissary corps, the elite infantry of the Ottomans, brought Murad II back to power in 1446, although many officials had considered him to be the actual ruler prior to this date.

Although deposed, Mehmed II remained active in the affairs of the state because Murad II viewed Mehmed II as his successor. As such, Mehmed II accompanied his father on campaigns in the Balkans on several occasions and ascended the throne for a second time on 18 February 1451 upon his father's death.

Ottoman relations with Serbia and the Byzantine Empire, with its capital in the city of Constantinople

(Istanbul in modern Turkey), had almost always been antagonistic. The transition in leadership from Murad II to a much younger Mehmed II seemed to present an opportunity to the enemies of the Ottomans. Almost immediately Serbia and the Byzantine Empire threatened to destabilize the region as Ibrahim, sultan of Karamanid (an independent emirate outside of Ottoman control), invaded Ottoman territories in Anatolia (in modern Turkey). Mehmed II dealt with both Serbia and the Byzantine Empire through force and diplomacy. Afterward Mehmed II began to plan for the destruction of the Byzantine Empire. He faced a difficult decision because a lengthy siege of Byzantium could draw Venice and Hungary into war with the Ottomans as well as draw a crusading army from western Europe. On the other hand, the empire of Byzantium (by this time, basically comprising the city and few outlying regions) continued to take every opportunity to meddle in Ottoman politics. After considering the advice of his counselors, Mehmed II proceeded with the siege, confident in the ability of the Ottoman heavy artillery. Indeed, the siege of Byzantium lasted less than two months, ending on 29 May 1453.

Although the city suffered enormous damage during the siege, Mehmed II spent considerable time and wealth rebuilding and repopulating it. The capture of the city and the fall of the Byzantine Empire enhanced Mehmed II's prestige as a *ghazi* (holy warrior). Indeed, the concept of *ghazi* became the theme of the Ottoman sultans, who used it even to legitimize themselves above other Muslim rulers such as the Mamluk sultans of Egypt and Syria and the Turkmen rulers who challenged the sultan's authority. Furthermore, Mehmed II also took the title of "Qaysar" (Caesar), thus placing himself as the heir to the Roman Empire

Giovanni Bellini, *Sultan Mehmet II* (1480). Oil on canvas.

and successor of the Byzantine Empire and legitimizing his claims to former domains of the empire in the Balkans and Mediterranean Sea.

By legitimizing his authority in both Islamic and European territories, Mehmed II sought to centralize power under him in the Balkans and Anatolia. After the fall of Byzantium in 1453, Mehmed II focused his efforts in the West. He established Ottoman control over most of the Balkans, including Serbia and Bosnia, as well as Greece. His activities, however, directly clashed with the interests of Hungary and Venice and resulted in the appropriately named Long War (1463–1479) against the two European powers.

Hostilities with Hungary continued beyond the war until Mehmed II's death, and Venice suffered greatly from the war, not only in loss of territory, but also in trade. Mehmed II simultaneously expanded the empire by conquering Trebizond on the northern coast of Anatolia as well as by turning the Black Sea into a virtual Ottoman lake.

Mehmed II's actions in Europe and the Middle East led states in the Levant (countries bordering on the

eastern Mediterranean) and Venice to form a loose alliance against the Ottomans. Although Mehmed defeated Karamanid and annexed its territory, this action led him into conflict with the Aq Qonyunlu (White Sheep) Turkmen confederation as well as the Mamluk sultan in Syria and Egypt.

In the context of world history Mehmed II is most notable for establishing the Ottoman Empire with its center in the Balkans and Anatolia. This establishment through the ideological mantle of his role as a *ghazi* would color Ottoman actions afterward. The transition of the sultan as the leader in war against non-Muslims diminished the influence of the frontier *begs* (lords—primarily nobility with a military function) who had previously held an immense amount of prestige as *ghazis*. Furthermore, by centralizing power, Mehmed II reduced the power of the local aristocracy and turned more territory into the direct service of the state.

Mehmed II also accepted into his service men of various nationalities and religions, preferring merit and talent to other qualifiers. He also instituted new legal codes based on his power as sultan that served as the core of Ottoman laws well into the seventeenth century.

Mencius

(c. 371–c. 289 BCE)

CHINESE PHILOSOPHER

The Chinese philosopher Mencius (c. 371–c. 289 BCE) was a follower of Confucius who advocated benevolent government based on the natural moral goodness of humankind. East Asian culture was greatly influenced by the teachings of both men.

Meng Ke, commonly referred to in the West as Mencius, the Latinized form of his title Mengzi (“Master Meng”), was a philosopher, itinerant official, and teacher during China’s chaotic Warring States period (475–221 BCE). As had been the case with Confucius, Mencius had very limited success as an administrator and court adviser. But he was a successful teacher, and his ideas, as recorded in the book that bears his name, later played a central role in the development of Confucianism—a philosophy that remains an important component in the culture of East Asia.

Born in the minor state of Zhou, located at the base of the Shandong Peninsula in eastern China, Mencius is said to have received his earliest education from a disciple of Kong Ji, or Zi Si, the grandson of Confucius. As a young man, Mencius obtained a position at the court of the local ruler, King Xuan of the state of Qi. Here the young philosopher advised the king by citing examples of moral and virtuous behavior from the age of the ruler-sages Yao and Shun, and from the ancient Xia, Shang, and Zhou dynasties. Given that this was a time characterized by warfare, intrigue, and shifting political alliances, it is not surprising that Mencius’s emphasis on the ideals of humanity, benevolence, and righteousness failed to find a sympathetic ear at the Qi court. While other philosophers and advisers, such as the strategist

Sunzi, encouraged warring kings to strengthen their administrations, to seek weaknesses in their opponents, and to utilize every tactic possible in order to protect and enlarge their kingdoms, Mencius urged rulers to seek peace, to lead by moral example, and to strive to recreate the golden age of the past. While Mencius was a respected philosopher and welcomed by the rulers of several states during his life, only one, King Hui of the Liang in the state of Wei, followed his advice. When King Hui died, Mencius, then forty years of age, withdrew from public life and worked along with several of his disciples compiling his writings and drafting commentaries on earlier texts.

In his writings Mencius emphasized two principles as the keys to restoring order and harmony to society. The first was *jen* (humanity, benevolence). The second concept was *xiao*, or filial piety, which was derived from his belief in the larger principle of *yi* (righteousness, duty). Mencius placed even greater emphasis on the importance of filial piety than Confucius, perhaps in an effort to counter the beliefs of the followers of Mozi, a rival philosopher who was an exponent of universal love. The concepts of *jen* and *xiao* were meant to shape not only a person’s immediate familial relationships, but also the relationship between a ruler and his subjects. A king was to be noble and to treat his subjects as his own children, providing them with security, guidance, and tempered discipline. In return, the common people were to be obedient and loyal to their ruler. Although a socially conservative philosopher, Mencius added a new component to the Confucian ideology that led some to consider him and his ideas dangerous. This more radical idea was the concept of the Mandate of Heaven, that the ruler’s family had been sanctioned

To act without clear understanding, / to form habits without investigation, / to follow a path all one's life / without knowing where it really leads— / such is the behavior of the multitude. • Mencius (c. 371–c. 289 BCE)

Mencius's teachings stressed benevolence and righteousness.

to rule by a divine power. If a ruler was an able and benevolent administrator who governed his people well, then he would retain the mandate. But should the ruler prove to be incompetent, or worse, morally corrupt and a despot, the mandate could be revoked and his subjects would then be free to overthrow him and his family.

As a Confucian philosopher, Mencius was opposed to other contending schools during the Warring States period. His beliefs, as detailed in the book that bears his name, played a key role in the development of Confucian philosophy during subsequent Chinese history. Zhu Xi (1130–1200), a scholar of

the Song dynasty (960–1279), combined the texts of Confucius's *Lunyu* (*Analects*) with *The Book of Mencius*, *Da Xue* (*Great Learning*), and *Zhong yong* (*Doctrine of the Mean*) to form the Four Books. This collection, together with the Five Classics of ancient Chinese literature, formed the basis for the traditional Confucian education system and was a body of work that was memorized by seven centuries of Chinese scholars. The civil service examinations that recruited China's imperial bureaucracy during the Song, Ming (1368–1644), and Qing (1644–1911/12) dynasties were heavily influenced by the ideas of Mencius and his followers.

Mercantilism

Mercantilism describes the economic policies of the major European states from the sixteenth to the eighteenth centuries, in a period when rivalries among new national monarchies were increasing along with Europe's role in world trade. A variety of sixteenth- and seventeenth-century thinkers defined the principles of mercantilist economics.

The sixteenth- and seventeenth-century thinkers who shaped the concept of *mercantilism*—and the economic policies it instituted in the European states affected by rival monarchies and increasing trade—argued that there was a fixed amount of wealth in the world. Each country should obtain as large a share of this wealth as possible, by active government policies that limited imports and sought to promote exports. High tariffs were an essential part of the mercantilist strategy. Pursuit of colonies played a role as well, while also dictating that the colonies be made insofar as possible a source of raw materials (which would therefore no longer have to be imported from outside the national system). Mercantilist ideas also prompted efforts by the British to reduce the import of manufactured goods from territories like India, in favor of their own production. Mercantilist policies prompted governments to try to set up new manufacturing plants that could both satisfy national needs and provide possible exports. In the absolutism of late-seventeenth-century France, the state undertook some of these ventures directly. Mercantilism also influenced the creation of some of the great state-affiliated commercial ventures, like the East India companies of Britain, Holland, and

France, designed to push colonial acquisitions and expand secure sources of supply.

Many states participated in mercantilism because of its military implications: successful acquisition of a larger share of the world's wealth would enhance the tax base and at the same time weaken competitors. Other states, less aggressive, pursued mercantilism for its presumed economic benefits, as in eighteenth-century Sweden, which actively encouraged exports and set up colonial commercial companies to trade with Africa and the West Indies. Switzerland in the eighteenth century translated mercantilism into government efforts to encourage sheep growing, to reduce dependence on imports of wool. The approach, in other words, had wide applicability and credence in early modern Europe. Mercantilism also related to government efforts to encourage population growth (a larger labor force would contribute to the national economic effort) and to import skilled foreign workers and businessmen.

The most systematic implementation of mercantilism undoubtedly occurred in the seventeenth century under Jean-Baptist Colbert in France, where it resulted in high tariffs, promotion of internal industry, and an effort to reduce internal barriers to trade. Many historians have argued that mercantilist burdens help explain why French economic dynamism began to lag in comparison with Britain, which was also affected by mercantilist thinking but less committed to state regulation. But mercantilism defined key Prussian policies under Frederick the Great and also affected eighteenth-century Austria, where its principles were expressed in the related movement called cameralism. Efforts to enforce mercantilist

George Webster, *Merchant Ship and Fishing Vessels off the Dutch Coast* (early 18th century). Oil on canvas.

policies more fully on colonial North America increased tensions between Britain and the colonists after 1763. Mercantilist thinking showed up again in Napoleon's construction of his Continental System, designed to use tariffs to attack British economic and military power.

Economic theorists began to attack mercantilist assumptions in the mid-eighteenth century, arguing that too much state regulation hurt rather than helped the economy and that the idea of a finite amount of world wealth was false. Debates over mercantilism spurred the rise of laissez-faire or liberal economic thinking. But mercantilist impulses continued to affect European policies, as in a penchant for high tariffs and continued colonialism. Some historians have dubbed the policies of the nineteenth-century decades of imperialism "neo-mercantilist" because of their relationship to older assumptions about state regulation and about

the relationship between military and economic competition.

Meroë

From the third century BCE, and for almost seven hundred years thereafter, Meroë was the most important city in northeast Africa, fostering extensive cultural and economic interaction between sub-Saharan Africa and Greco-Roman Egypt. Its tradition of urban life and state-level social and political organization survived the fall of the city and influenced Christian kingdoms that dominated the Nile Valley south of Egypt during the Middle Ages.

Meroë was the last capital of the kingdom of Cush, the earliest known imperial state in the interior of Africa. Located in the central Sudan on the east bank of the Nile south of the fifth cataract of the Nile and near the junction of the Nile and Atbara Rivers, Meroë sat astride important trade routes leading from the Nile valley to the Red Sea and from the southern Sudan to Egypt. Although the great slag heaps scattered over the site of Meroë suggested to early historians of ancient Africa that Meroë prospered as a center of iron manufacturing, more recent research indicates that Meroë's prosperity was based on its ability to control the supply of African goods such as gold, ivory, ebony, exotic animals, and slaves to Egypt.

The History of Meroë

Although Meroë was the southernmost civilized city known to ancient Greek geographers, knowledge of its exact location was lost until it was identified by the Scottish explorer James Bruce in 1772. Seven Greek writers are known to have written works devoted to Aithiopia, the Greek term for Cush. Only

meager fragments of these works remain, and the few inscriptions from the site are written in the still-undeciphered Meroitic language. As a result, reconstructions of the history of Meroë rely primarily on archaeological evidence. Unfortunately, the only major excavations undertaken at Meroë to this date—those conducted by John Garstang for the University of Liverpool between 1909 and 1914—were poorly managed and recorded.

The early history of Meroë is especially poorly known. Archaeological evidence indicates that a settlement already existed at Meroë in the eighth century BCE, but that Meroë only became a principal royal residence in the sixth century BCE. Cush was invaded by the Egyptian king Psamtek II in 593 BCE and again by the Persians in the 520s BCE. Neither of these attacks, however, reached Meroë, although Cush did recognize Persian suzerainty. Despite these events, the political and religious center of Cush remained near the fourth cataract of the Nile at the city of Napata.

The status of Meroë changed dramatically in the third century BCE. Attacked by Ptolemaic Egypt in the 270s BCE, Cush lost control of an important region called the Dodekaschoinos just south of the first cataract of the Nile together with valuable gold mines located in the eastern desert. The Cushite king Arqamani (reigned c. 218–200 BCE) led a revolt against Napatan domination that resulted in the transfer of the political capital and royal burial site south to Meroë. As a result of these developments, strong Ptolemaic political and cultural influence penetrated Cushite territory during the remainder of the third century BCE.

Relations between Meroë and Egypt remained tense but stable until the Roman conquest of Ptolemaic

Cushite power, until the Aksumite king Ezana conquered and sacked Meroë in the mid-fourth century. Although there is evidence of later Christian settlement at Meroë, its history as a major political center was at an end.

Government and Culture at Meroë

The government and culture of Meroë were a mixture of local and Egyptian traditions. The most obvious evidence of the Egyptian elements in Meroitic culture are the statues and pyramids of the kings of Cush, the huge Egyptian-style temple of the god Amon, and the walled compound beside the Nile that formed the core of the city and contained the royal palace and other government buildings.

Egypt in 30 BCE. A Roman invasion in the early 20s BCE temporarily made Cush tributary to Rome. Strong resistance by Cush, however, led to Roman withdrawal and the establishment of a de facto peace between Cush and Rome that lasted until the mid-third century CE.

The early centuries of the common era were the golden age of Meroë. Cushite territory extended from northern Nubia (a Nile Valley region comprising present-day northern Sudan and southern Egypt to approximately the Aswan Dam) to near modern Khartoum in Sudan. Trade with Roman Egypt flourished, and extensive temple building and agricultural development, including the construction of water storage facilities occurred throughout Cush. By the third century, however, Cush and Meroë were both in decline. The shift of the main trade route to Egypt to the Red Sea weakened Cush economically. At the same time, attacks by the Noba and Blemmyes, nomadic peoples from the western and eastern deserts, and by the neighboring kingdom of Aksum undermined

Although the Cushite kings' claim to be sons of Amon and their royal regalia both reflected Egyptian influence, uniquely Cushite were the preference given the son of a king's sister in the succession to the throne and the prominent role assigned to the queen and especially to the king's mother, who bore the title *kandake*. Some *kandakes* even ruled in their own name during the late first century BCE and first century CE. Local tradition also influenced religion in Meroë, most notably in the prominence of the lion-headed war god Apedemak, who functioned as the king's protector and was worshipped in a uniquely styled one-room temple that had no parallel in Egypt.

Meroitic elite culture was literate. Its unique alphabetic script was developed in the late third or early second century BCE. Consisting of twenty-three symbols adapted from Egyptian hieroglyphic signs, it was used for governmental, religious, and funerary texts written on a variety of media, including stone, wood, *ostrakoi* (pieces of broken pottery), and papyrus.

Decipherment of the Meroitic language will provide valuable insights into Meroitic history and culture.

For almost seven hundred years Meroë was the most important city in ancient northeast Africa. During that period, it fostered extensive cultural and economic interaction between sub-Saharan Africa and Greco-Roman Egypt. It also established a tradition of urban life and state-level social and political organization that survived the fall of the city and continued to influence the Christian kingdoms that dominated the Nile valley south of Egypt during the Middle Ages.

Mesoamerica

Mesoamerica (most of present-day Mexico and parts of Belize, Guatemala and Honduras) was one of the two regions in the Americas (the other being the Andes) where complex state societies developed before the arrival of the Spanish in the early sixteenth century. The long-term and extensive contact among peoples and states in the region influenced sociopolitical, cultural, and religious ideas in other regions to the south and north.

Mesoamerica designates a cultural region of Middle America prior to the Spanish conquest. The label was suggested by the anthropologist Paul Kirchhoff in 1943 and has come into general use since. Geographically, Mesoamerica included almost all of Mexico as well parts of what are now the nations of Belize, Guatemala, and Honduras. As a cultural region, Mesoamerican states shared a cluster of characteristics (with some regional variation) that distinguished them from societies in regions to the north and south. These included a state-level political organization with power resting in city-states, theocratic rule, monumental architecture and sculpture, and an economy based on the acquisition of food through taxation and warfare. Mesoamerican states typically had a hierarchical social structure with two primary classes, nobles and commoners, the latter being mainly farmers, and a third category of occupational specialists that included priests, scribes, potters, warriors, and sculptors who served the state. The best known of the Mesoamerican states are those of the Olmecs, Maya, and Aztecs. These ancient states and their monumental art and architecture have become part of modern Mexican national identity, while the

remains of their cities and buildings are major tourist attractions.

From the perspective of world history, Mesoamerica is important not so much because it was a distinct cultural region but because it was one of the two regions in the Americas (the other being the Andes) where complex state societies developed, because of the long-term and extensive contact among peoples and states in the region, and because of its influence on other regions to the south and north. Mesoamerican states differed from early state-level societies elsewhere in the world in that the domestication of large animals did not occur, despite the domestication of plants. In addition, most Mesoamerica states had less interest in territorial expansion than in maintaining economic control over subjugated communities.

Over the more than three thousand years during which states emerged, expanded, contracted, and disappeared in the region, large and complex trade networks developed that crisscrossed Mesoamerica and extended at times south into present-day El Salvador and north to the Great Lakes. These networks played a leading role in creating a cultural unity across the region that survived the passage of time and the fall of empires. Systems of exchange in Mexico emerged about 2000 BCE, when chiefdoms in several locations began exchanging precious metals, obsidian blades, pottery vessels, and ritual items such as shell ornaments and turtle shells. Most of these trade goods were used in ceremonies and were likely produced by specialists for the rulers. Exchange of objects for ceremonial use accelerated during the Classic period (c. 250 CE–900 CE), when Mayan rulers accumulated feathers, precious stones, foodstuffs, and obsidian objects as signs of their wealth and power.

In central Mexico, in the powerful city-state of Teotihuacán, the focus was on production and trade, with numerous craft workshops creating obsidian objects and pottery for trade throughout Mesoamerica. Also present were professional merchants who coordinated trade among different city-states. The Postclassic period (900 CE–1521 CE) saw a dramatic increase in exchange across much of the region. Not only goods but also ideas—art style, religious beliefs, forms of government—spread across the region, and a few hundred years before the Spanish conquest, professional merchants, marketplaces, and money were in use.

Periodization

Archaeologists conventionally divide Mesoamerican prehistory into four periods: Archaic (c. 15,000–c. 1600 BCE), Preclassic or Formative (c. 1600 BCE–c. 250 CE), Classic, and Postclassic. Cutting across these periods is a geographic classification of Mesoamerican societies as lowland or highland.

Mesoamerica was settled about 13,000 BCE, and by about 7000 BCE the region was widely inhabited. These first settlers were foragers whose diet was rich in animal protein. During the Archaic period, first gourds and then maize and beans came under cultivation. By the end of the Archaic period people were living in small villages with local burials and signs of ancestor veneration.

States in the Preclassic and Classic Periods

The Preclassic period saw a significant increase in scale, with the development of larger and more permanent settlements and the rise of political leaders, social distinctions based on wealth and power, more intensive farming, and the emergence of exchange networks. The most important Preclassic society was the Olmec culture (1200–400 BCE) on the southern Gulf Coast of Mexico. The key Olmec centers were at San Lorenzo and La Venta, where archaeologists have found remnants of monumental architecture,

evidence of a complex religious system and extensive exchange for luxury items used in public rituals, and distinctive large, carved stone heads. By the close of this period, Mesoamerica was dotted with city-states supported by surrounding farming communities and trading with one another. The Zapotecs in the valley of Oaxaca developed the first writing system and calendar at their regional center of Monte Alban.

Teotihuacán, a large city-state in central Mexico, spanned the Preclassic and Classic periods. It was the largest city in the Americas and one of the largest cities in the world in the first millennium CE. It began to develop as a population center in about 200 BCE and flourished from about 150 CE to 750 CE, when the center of the city was burned. From that time on Teotihuacán ceased to be a major urban center. It may have been home to as many as 200,000 people at times, with its inhabitants depending on foodstuffs raised using irrigation and terraced agriculture. The city was built on a grid plan, with a major north-south street. Most buildings in the center were large apartment blocks that housed the residents, probably localized on the basis of kinship. There were also numerous craft shops, merchant facilities, and public and ceremonial structures. The rulers never controlled a large territory, but the cultural influence that Teotihuacán spread through trade networks was

The island of Janitzio in Lago de Patzcuaro is now a major vacation venue. Patzcuaro was once the capital of the late Postclassic Purepecha state in central Mexico.

enormous. Its distinctive aesthetic style, displayed in pottery, sculpture, murals, and carvings, spread throughout Mesoamerica, and its urban planning and religion were models for the latter Aztec Empire.

While Teotihuacán emerged and flourished in central Mexico, what has come to be labeled the Classic Maya civilization emerged and flourished in the lowlands of Mexico and Guatemala. The first Mayan communities emerged between 1000 and 400 BCE. These small villages became larger ceremonial sites, supported by a lucrative trade in honey and salt. Maya civilization flourished from about 300 to 900 CE, with major centers at Cobán, Tikal, Palenque, Calakmul, and Copán. A hereditary elite ruled these city-states and maintained an uneasy balance of power based on marriage alliances, trade, and warfare. Eighty percent or more of the people were rural farmers, who supported the cities and ceremonial centers through intensive agriculture. The Maya are notable in human history in the Americas for developing a sophisticated and accurate calendar, a system of writing recorded in stone and in bark texts, and large ball courts where a game that seems a mix of soccer and basketball was played, sometimes to the death. Unfortunately, the Spanish, in an effort to destroy the Mayan religion, destroyed almost all Maya written texts.

The Maya city-states began to collapse in the eighth century, with those in the south disintegrating as viable political units first and those in the northern lowlands lasting to about 1000 or later. Their collapse marked the end of the Classic period. The question of why the sudden and widespread collapse took place has intrigued archaeologists for decades. Most now

agree that no single factor was to blame, but that environmental change, population pressure, political instability, warfare, and depopulation all played a role, affecting the southern and northern lowlands somewhat differently.

States in the Postclassic Period

The early Postclassic period was marked by the appearance of several regional city-states, including the Toltecs (centered at Tula in Central Mexico), the Mixtecs (in Oaxaca), the Tarascans (in Michoacán), and the northern Maya center of Chichén Itzá. The final and largest preconquest state was the Aztec Empire, centered in the Valley of Mexico, which grew to be the largest tribute-based empire in the Americas. The Aztec Empire ruled much of central and southern Mexico from 1430 until 1521. Its capital city of Tenochtitlán was modeled on Teotihuacán, and its religion, too, resembled that of the earlier city-state, while its political system was based on the Toltec system at Tula.

Mesoamerica after the Spanish Conquest

At the time of the Spanish conquest, most Mesoamericans were small-scale farmers. The Spanish rulers established the *encomienda* system, whereby districts were put under the control of colonists who exploited indigenous labor for work on farms and in mines. Catholic missionaries did their part to convert the native populations to Roman Catholicism, although

The remains of a Tarascan ceremonial center in central Mexico.

some missionaries also tried to protect them and end harsh labor practices. The indigenous population was severely damaged by disease and the harsh colonial conditions, and some people sought refuge in isolated villages. In the 1880s the *encomienda* system gave way to the hacienda system, which saw the remaining good Indian land transferred to the government and sold for commercial use. Indigenous peoples became even more isolated in rural communities, some surviving on poor land as subsistence farmers while many others labored in the hacienda fields.

The Mexican revolutions of the early twentieth century restored some land to native peoples, and more was returned in the land reforms of the 1930s. Nonetheless, most rural indigenous remain impoverished farmers, with most land used for commercial farming by mestizos (people of mixed European and Indian descent), who looked down upon Indians as inferior. Since the 1970s there have been a series of peasant revolts over land rights involving Indians in rural Mexico. There has also been substantial migration to cities, other regions of Central America, and the United States.

In the twenty-first century, Native Americans make up 9 percent of the population of Mexico and 44 percent of the population of Guatemala. In rural

areas, indigenous identity is based on speaking a native language; subsistence farming based on maize (corn), beans, and squash; weekly outdoor markets; traditional dress style; use of traditional techniques to produce traditional craft items; and adherence to a religion that combines the indigenous religion with elements of Roman Catholicism. Most indigenous peoples affiliate more strongly with their village than with a region or larger ethnic or language group.

Many of the indigenous groups present in Mesoamerica at the time of the conquest live on, though more as language groups than as distinct, unified cultural entities. Among the major groups are those associated with the Aztec Empire—Nahua (Mexicans), Otomi, and Mazahua near Mexico City—other surviving groups include Tarascans (Purepecha) in central Mexico; Zapotec, Mixtec, and Mazatec in Oaxaca; and some twenty-one Mayan groups in the Yucantan, Belize, and Guatemala.

Mesopotamia

Ancient Mesopotamia (now Iraq), one of the world's longest (almost three thousand years old) and influential civilizations, remains the most concentrated archaeological site on Earth, a fact that provoked outcry from researchers at the outset of the 1991 bombing of the Persian Gulf known as Operation Desert Storm. Throughout the history of Mesopotamia, its people interacted vigorously with their neighbors, warring, trading, migrating, and sharing ideas.

Mesopotamia, the ancient name for the land that is now Iraq, flourished as what was recognizably the same civilization for almost three thousand years, from 3200 BCE, when the people of the region invented a system of writing and the first cities arose, to 330 BCE, when the Persian Achaemenid Empire was conquered by the Greeks. Throughout those centuries, the people of Mesopotamia used the same writing system, worshiped the same gods, lived in the same cities, and traded the same types of goods. Mesopotamia was where some of the most important innovations in human history occurred first: cities, the wheel, the plow, written law, irrigation agriculture, mathematics, and imperial government. Although peoples elsewhere in the world developed many of these innovations at other times, Mesopotamia left an impressive legacy for the histories of Europe and Western Asia.

Mesopotamia was also a center for trade and for contact between cultures. Artifacts from prehistoric sites reflect the fact that long-distance trade was taking place long before anyone could record the transactions. Throughout the history of Mesopotamia, its

people interacted vigorously with their neighbors, warring, trading, migrating, and sharing ideas.

Mesopotamia had many names during the height of its civilization, but *Mesopotamia* was not one of them. The ancient Greeks named the valley of the Euphrates and Tigris rivers “the land between the rivers” (*meso* = between, *potamia* = rivers), and the name has stuck. In the third and early second millennia BCE, there was no name for the region as a whole. The southernmost part, the area closest to the Persian Gulf, was called Sumer. Slightly to the north of Sumer, where the Tigris and Euphrates flow closest together, was the land of Akkad. Later, when these two lands were united under a single government, they came to be thought of as one state, which we call Babylonia. North of Babylonia on the Tigris was a land that had a deep historic connection with Babylonia. It was called Ashur, or Assyria, in our modern terminology. But rarely during ancient history was the land of Mesopotamia a political whole.

Prehistory

Northern Mesopotamia, the region that became known as Assyria, is a land of rolling hills that are green and covered with wildflowers in the spring but dry and brown in the summer. Southern Mesopotamia—Babylonia—is flat, hot, and dry. It would be an inhospitable desert if it were not for the two rivers that flow through it. The Tigris, the eastern of the two, is fast moving and often dangerous, whereas the Euphrates is a gentler river surrounded by rich silty soil. The earliest settlers in southern Mesopotamia, arriving around 5000 BCE, chose to live on the banks

of the Euphrates, as did most people who lived in the south in ancient times.

Early communities were small, and their inhabitants probably survived by fishing, hunting gazelles and birds, and gathering plants, along with practicing small-scale agriculture. Agriculture had already developed in the foothills to the northwest of Mesopotamia, in Syria, and was brought to the south by settlers, who introduced domesticated grains—wheat and barley—and animals, such as goats, sheep, oxen, and pigs. The village fields might have been located in old marshlands, still wet enough to support agriculture without additional watering, or the villagers might have watered their fields using simple irrigation ditches.

Over time, the communities began to grow, requiring larger irrigation ditches and more cooperation between families in order to feed the population. From earliest times the Mesopotamians who occupied these communities seem to have understood the importance of irrigation technology. They could not allow the Euphrates to overflow its banks, for fear of the river moving to a different location, perhaps miles from their town, when the flood receded. The annual flood also came at an awkward time in the agricultural calendar and might destroy new plants if allowed to cover the fields. So the southern

Mesopotamians built up artificial levees along the riverbanks, and they dug canals and reservoirs to cope with the floodwaters. Although archaeologists have found evidence of a few devastating floods in Mesopotamian prehistory, by historic times the annual floods seem to have been brought under control and rarely presented a danger to the people or their communities.

Urban Revolution

By 3200 BCE the landscape had changed dramatically in southern Mesopotamia. Up and down the banks of the Euphrates were big cities, each one home to 10,000–25,000 people, the first cities on Earth. Each had a big temple complex in the center, surrounded by mud brick houses built in rows along narrow streets. Around the cities were canals and irrigation ditches, bringing river water to long, rectangular fields of wheat and barley. Gardens of palm trees spread along the levees of the river. Most city residents were farmers who went out to work their fields during the day, but some residents engaged in specialized professions; these included metal workers, potters, textile weavers, priests, and traders. This was the time when some people began to become rich while others fell into debt and poverty.

This period, known as the Uruk period, also witnessed the invention of the wheel, the plow, and the cylinder seal for marking property. With the invention of metallurgy, copper bowls and, later, bronze weapons and tools were forged.

Someone must have been in charge of the individual cities, though archaeologists are unsure who. Some sculptures from the Uruk period feature men who wore long beards and broad belts. These must have been important individuals to have warranted having their portraits sculpted. It is possible, since temples dominated the cities, that these were priest-rulers.

The cities of the south were certainly in contact with one another, but they also had connections with other cities at a great distance, in Syria to the northwest and Assyria to the north. Indeed, the settlements of the Uruk period seem to have been colonies established by southern cities as centers for an extensive trade network. The styles of architecture and pottery in the colonial outposts are almost identical to those in the south and contrast dramatically with the material culture in surrounding towns and villages.

One of the most important innovations of the Uruk period was the invention of writing. The first signs were pictures, drawn carefully on clay tablets, but the pictures soon became simpler and unrecognizable as objects. The signs were drawn with straight lines, impressed by a stylus with a distinctive end that resulted in small wedges at the end of each line. These wedges give the script its modern name, cuneiform, from the Latin word *cuneus*, meaning “wedge.” Some of the cuneiform signs stood for whole words, but most were phonetic symbols that represented the sounds of the language.

Around 2900 BCE the first kings took power in Sumer and in Akkad to the north, marking the beginning of the early dynastic period of Mesopotamian history. Each of the major cities had its own king, and each city-state was also home to a god. The major temple in each city was where the city god and the god’s spouse were believed to live. For example, the city of Nippur was the residence of the king of the gods, Enlil. The city of Ur was home to the moon god,

Nanna. The people of Sumer and Akkad believed in all these gods, but had a special connection with the god of their own city, by whom the king of the city claimed to have been chosen by the god to rule.

Akkadian Empire

Throughout the early dynastic period, city-states warred with one another, sometimes forming leagues, sometimes forced to submit to rule by another city. But it was not until the twenty-fourth century BCE that the entire region was brought under the rule of a single government. Sargon of Akkad (reigned c. 2334–2279 BCE) forged the first empire to include people of different nationalities. He dominated the Sumerian-speaking peoples of the south, the Akkadian-speaking peoples of the center, and the Eblaite- and Hurrian-speaking peoples of the northwest. He claimed to have conquered from the Upper Sea (the Mediterranean) to the Lower Sea (the Persian Gulf). Sargon also boasted that he sponsored trade on a large scale, welcoming ships from as far away as Dilmun (Bahrain), Magan (Oman), and Meluhha (the Indus Valley) to his ports. Archaeological evidence supports this claim, as objects from these regions have indeed been found in Mesopotamia, and Mesopotamian artifacts have been found in lands bordering the Persian Gulf and in the Indus Valley.

Sargon’s religious innovations included making his daughter, Enheduanna, the high priestess of the moon god at Ur. She was first of many royal women to hold this powerful position, and was also the author of many hymns to the gods.

Sargon’s native language of Akkadian was used for the first time in written documents, but it had long been spoken throughout Mesopotamia and was gradually replacing Sumerian as the spoken language of the people, even in the south. Akkadian is a Semitic language, related to modern-day Hebrew and Arabic.

Third Dynasty of Ur

Sargon’s great empire was maintained and even enlarged under the rule of his grandson, Naram-Sin

(c. 2254–c. 2218 BCE), but it collapsed under an invasion around 2150 BCE. The invaders were Gutians from the mountains to the east, whom the Mesopotamians viewed as only partly human—their language sounded to Mesopotamian ears like dogs barking.

It was not until 2112 BCE that the land was once again united, this time under the third dynasty of kings from the southern city of Ur. This era is often known as the Ur III period. Unlike Sargon, the Ur III kings did not emphasize their military conquests. Instead, they focused on peaceful, organizational developments. They standardized weights and measures; introduced a staggeringly complicated bureaucracy, in which, for example, every animal dedicated to a temple was recorded in daily and monthly records; built the first ziggurats (monumental stepped towers associated with temples to the gods); and tried to revive Sumerian as the language of literature and administration. Thanks to their scribes, many of the classics of Sumerian storytelling were recorded and kept for future generations.

Shulgi, an Ur III king whose long reign lasted from 2094 to 2047 BCE, also created the first written set of laws. This achievement has often been credited to his father, King Ur-Nammu (reigned 2112–2095), but Shulgi is now thought to have been the one responsible. Only thirty-seven of the laws survive; but this is enough to show that most crimes were punishable by fines and that a court system was already in effect.

The kings of the Ur III period seem to have had less contact with the lands of Magan and Meluhha than did the Akkadian kings, but they had diplomatic ties with kings in Elam, in what is now eastern Iraq and western Iran. In fact, several princesses of Ur were married to kings and princes of Elam in dynastic marriages that aimed to strengthen ties between the states.

Old Babylonian Period

Mesopotamia was constantly subject to immigration as people from neighboring lands moved to the river valley, settled, and adopted Mesopotamian ways. The valley was not protected from the outside

by any natural barrier, or even any clear political border, and its agricultural wealth must have made it a magnet for people from areas with less fertile soil. One such people were the Amorites, who came from somewhere to the west of Mesopotamia, though historians are not certain where. They began as immigrants, but ended up, around 2000 BCE, as invaders, taking over control of Mesopotamia from the weakened kings of the third dynasty of Ur. Amorite dynasties conquered and then ruled some major cities and some lesser-known ones. One of the latter was Babylon, which only became an important place under its Amorite kings. The kings of Babylon (Hammurabi being perhaps the most notable) had a particularly stable dynasty, with son taking over from father on the throne for at least seven generations, and perhaps as many as eleven.

Late Bronze Age

In 1595 BCE Babylon was attacked and sacked by an army from Hatti (modern Turkey). The Hittites, as the people of Hatti were called, were relatively new to power, and it was two centuries before they became a major international force, but their raid into Mesopotamia had a devastating impact on the Babylonians. The land fell into a dark age, during which few cuneiform documents were written. By 1500 BCE a new immigrant dynasty was on the throne—the Kassites. Like the Amorites before them, they adopted Mesopotamian gods and Mesopotamian dress. They used Mesopotamian languages (Sumerian and Akkadian) in their administration and inscriptions, and only used their native language to write their personal names (though they may well still have spoken in Kassite). The Kassites oversaw four centuries of peace and prosperity during the late Bronze Age, when Babylonia was in close diplomatic and economic contact with the other great powers of the region: Egypt, Hatti, and Mittani (a state that encompassed Syria and the northern part of Mesopotamia that became Assyria).

The kings of these lands married one another's daughters, sent one another luxury gifts, and kept

The fox could not build his own house, and so he came to the house of his friend as a conqueror. • **Sumerian Proverb**

ambassadors and messengers busy traveling for months between one another's courts with letters and news. The lands also periodically went to war, though Babylonia seems for the most part to have stayed out of military conflicts.

Mittani suffered a setback when its eastern half, Assyria, asserted its independence in the fourteenth century BCE. By 1250, Mittani was gone, swallowed up by the imperial ambitions of its neighbors. By around 1100 BCE, all the great powers had fallen into decline, even the upstart Assyria. Many theories have been put forward to account for this disaster at the end of the Bronze Age, including climate change, invasion, internal revolt, even epidemic disease, but whatever the cause, the outcome was a massive change in Near Eastern political and economic structures. Small kingdoms became the rule of the day, and for over a century scribes seem to have been writing nothing at all (though someone was keeping the cuneiform tradition alive somewhere, because some centuries later cuneiform sources reappear, so we have almost no clue as to what was happening.

Neo-Assyrian Empire

In the ninth century BCE Assyria began to reassert its dominance over northern Mesopotamia. Its kings were devoted to their state god, Ashur, and put great value on military prowess. They built up armies and sponsored the development of new military technologies (such as the siege machine and battering ram) that enabled them to expand the borders of their kingdom to the east, north, and south.

Like earlier Mesopotamian emperors, the kings of Assyria were masters of organization. They divided their empire into provinces, each ruled by a governor; they posted garrison troops in these provinces, ready to put down local rebellions, and they kept in close contact with even the most distant reaches of the empire. Hundreds of letters to and from the kings of Assyria have been excavated from their palaces, showing that the kings were kept well informed about even apparently trivial matters across their realm.

The Assyrian kings did not hesitate to use force to extract tribute from rebellious cities or to punish rebel leaders. They also deported whole populations across the empire in order to break up possible revolts and to settle tax-paying subjects in areas with agricultural potential. The huge wealth that flowed into Assyria from taxes and tribute was used to build spectacular palaces decorated with stone relief sculptures of the kings' victories. Ashurbanipal (reigned 668–627 BCE) created a vast library of cuneiform documents, literary works copied from originals that he had scribes seek out in cities throughout Assyria and Babylonia. The study of astronomy, mathematics, and other sciences blossomed under the patronage of the kings of Assyria.

At its height, Assyria shared with Babylonia a common culture, a common written language (Akkadian, though Aramaic was increasingly the spoken language in both regions), a single writing system, and a shared belief system. Their economies were intertwined, and yet they were ambivalent about one another: sometimes they were at war, sometimes Assyria dominated Babylonia; sometimes they managed a fragile peace under separate governments.

Neo-Babylonian Empire

In 612 BCE the Assyrian Empire fell to the combined forces of its neighbors to the south and the east—the Babylonians and the Medes. Its cities were sacked and burned, and Assyria never again became an important player on the world stage. For seventy-five years the center of Mesopotamian culture returned to Babylon. Nebuchadnezzar II (reigned 605–562 BCE) enlarged and beautified the city with a huge palace, an embellished ziggurat to Marduk, magnificent city walls, and gateways several stories high decorated with brilliant blue glazed bricks and sculpted lions and dragons. Later classical historians even credited him with building the hanging gardens of Babylon, though there is no evidence of them from his reign.

The Neo-Babylonian kings, like their Assyrian forebears, extracted tax and tribute from their empire,

and even tried (unsuccessfully) to conquer Egypt. It was during the reign of Nebuchadnezzar that Babylon conquered the kingdom of Judah and many Jews, including the king, were taken captive to Babylon. But the Neo-Babylonian kings fell victim to their neighbors the Persians, situated in what is now Iran, during the reign of Cyrus II (reigned 559–c. 529 BCE). The Persian Empire, which stretched from the Indus Valley to Egypt, lasted until 330 BCE, when it fell to Alexander of Macedon (Alexander the Great, reigned 336–323 BCE).

Legacy

The Akkadian and Sumerian tongues faded from use during Persian and Greek rule, but although the civilization was forgotten for many centuries, its great innovations lived on. The Canaanites and Israelites had taken on many of the legal ideas from Hammurabi's laws, and from other Mesopotamian collections. These are reflected in the Biblical laws, which were never forgotten once they had been compiled. The Greeks learned mathematics and astronomy from the Mesopotamians and elaborated the sciences further. They also adopted Mesopotamian astrological ideas, military tactics, and artistic styles. It is from the Mesopotamians that we get the 24-hour day, the 60-minute hour, and the 60-second minute, and the 360-degree circle (their numerical system had a base of sixty). Our writing system is not directly descended from cuneiform, but the idea of writing down sounds, a concept common to both cuneiform and Egyptian hieroglyphs, inspired the creation of the alphabet. Even the very idea of urban living first developed on the banks of the Euphrates, as did many early experiments in how to govern. Mesopotamian civilization was one of the longest lasting and most influential in all of human history.

Metallurgy

Although metallurgy as a science is relatively recent, the knowledge of metals, their uses and properties, and the methods for obtaining and working with them date back to the origins of civilization. In the twenty-first century the complexity and speed of technological change, and the most recent progress in science and engineering, fosters the constant development of new materials and processes.

Archaeological evidence suggests that the first metals known to man were those presented more frequently in nature in their native or metallic state, that is to say gold, copper, silver, and meteoric iron. It was probably in Anatolia that metals were used for the first time, around 7000 to 6500 BCE. It is possible, nevertheless, that metals were first employed independently in diverse areas, at dates even earlier than those conventionally accepted.

Metallurgy in Prehistory

In its early stages, interest in native metals would likely have been linked more to their aesthetic characteristics (brightness, color, weight) than to their practical possibilities. Their external appearance made them attractive and easily recognizable, and they were used for artistic, ornamental, or magical/religious purposes. During this period, when humanity was still in its prehistoric phase, native metals were worked making use of mechanical methods, in accordance with techniques and abilities similar to those used by primitive humans to work stone, bone, or wood. Unlike these conventional materials, however, the malleability that characterizes metals made

it possible to fashion much more diverse, precise, and effective objects, including tools and weapons. In a more advanced era (c. 4000 BCE), the use of fire would allow the forging, casting, and molding of some of the metals already known (copper and gold), representing a new step in the development of metallurgy and the productive use of the metals.

The decisive advance, however, would take place once it was possible to obtain metals, initially copper, by reducing their corresponding mineral content by means of pyrometallurgical methods, around 3500 BCE, in the region of the Near East. Starting from that point, metallurgy combined its original mechanical procedures with the complex chemical processes that take place in a reduction furnace, which are much more difficult to observe and to control. This method laid the technical foundations of modern metallurgy, and its productive possibilities, until then limited by the shortage of native metals deposits, were increased.

It is difficult to determine in what way and at what moment early metallurgy spread through different cultures and geographical areas. Nevertheless, it is known that by 3000–2500 BCE copper metallurgy extended over an extensive area that stretched from the Iberian Peninsula in western Europe to China on the Asian continent. Later it penetrated to the British Isles and Scandinavia (c. 2000 BCE) and Japan (c. 800 BCE). On the American continent there exists archaeological evidence of the use of native copper by the North American Indians toward 3000 BCE. However, pre-Columbian civilizations didn't come to control metallurgic techniques properly until a very late date, around the eighth century CE.

The new metallurgical procedures, almost always developed in a fortuitous and experimental way and

involving the use of fire, not only allowed an increase in the production and consumption of metals, but also opened new possibilities for improvement of their quality, adapted in each case to their application or final use. For example, objects made from pure copper were too soft; however, in combination with other metals their resistance and hardness could increase. By mixing copper and tin one could obtain an alloy, bronze, that was much more appropriate for the production of tools and weapons. The spread of this alloy, which was substituted for stone, ceramics, and other materials, in what is known as the Bronze

Age (c. 3000 BCE to c. 1000 BCE), was a decisive element in the development of the first civilizations and empires to arise in Asia Minor and in the eastern Mediterranean. This was followed by the discovery of other types of alloys whose exact composition was known only in an intuitive and approximate way.

Following the discovery of bronze, another metal had even more impact on the development of civilization—iron. Though it is one of the most abundant elements in nature (the fourth most abundant element in the world), it rarely exists in a pure state. Except for very small quantities of iron coming from

This series of drawings shows the variety of processes and products of metal working over time and across cultures: (1) nuggets of polished iron ore (Mississippian culture, Kentucky); (2) nuggets of flaked and rubbed iron ore (Mississippian); (3) nuggets of polished iron ore (Mississippian); (4) pieces of cold-hammered copper (Great Lakes); (5) copper arrowhead and sheet cold-hammered (Mississippian, Ohio and Michigan); (6) copper sheets cold-hammered and punched (Mississippian, Wisconsin); (7) copper sheets hammered, crimped and corrugated (northwest coast of North America); (8) copper cast as a half-socketed axe or adz (Wisconsin); (9) bronze hatchet blades (Europe); (10) cast-iron fish (Europe); (11) forged metal (West Africa); (12) metal worked on anvil (West Africa); (13) metal pieces welded together by firing and hammering; (14) metal pieces riveted together; (15) metal pieces of a bell joined by soldering or brazing.

meteorites—which in fact are natural alloys of iron and nickel—iron metallurgy had to be developed once the techniques for reduction and treatment of minerals were already known. It was probably discovered for the first time within the Hittite Empire, south of the Black Sea, around 1500 BCE, although we cannot disregard independent discoveries in different areas and times.

Contrary to the metals known until then, iron could not be melted and cast in furnaces whose maximum temperature was only about 1,000°C. Due to this factor, its production was not possible by means of the techniques known in the Bronze Age. Instead of liquid metal, the blacksmith obtained a spongy mass whose metal particles appeared dispersed and blended with the impurities of the mineral and the remains of the charcoal employed in combustion. To finally obtain the iron, it was necessary to develop a new process of hammering this spongy mass by means of which the slag was eliminated and the metallic particles compacted. The product obtained this way, which was practically pure iron, remained too soft and didn't offer significant advantages over bronze. It was necessary to heat it again and to forge it until it absorbed a certain percentage of carbon in its surface, a process known as carburization or cementation. The steel obtained in this way could be tempered by being introduced into cold water so that it became even harder. These new techniques constituted complex and laborious processes whose development and diffusion took place very slowly. In Europe their spread occurred throughout the Mediterranean region starting in 1000 BCE and arriving in England toward the year 300 BCE. In the East we know that iron metallurgy was introduced in India around 800 BCE and in China around 600 BCE. In China, however, the technical evolution was more rapid thanks to the discovery of the blast furnace and cast-iron production around 200 BCE; these techniques were not used in Europe until the fifteenth century CE.

Important economic and social repercussions were associated with the advance of primitive metallurgy and the use of metals. With time, the extraction and initial treatment of the minerals would become an

independent activity. Forging was probably one of the first specialized occupations. The mythology and legends of ancient peoples frequently reflect the vision that primitive communities always had of it as a mysterious and magic occupation, capable of transforming stones into metals and useful instruments. On the other hand, the use of metals, particularly iron, contributed in a decisive way to the progress of agriculture, the development of activities associated with sedentary cultures, the growth of the first urban nucleus (by its use in construction, transport, and so forth), and, of course, war.

Metallurgy in Antiquity and the Middle Ages

Once they had control of the techniques for producing iron, the forgers of antiquity had a much cheaper and more abundant metal than bronze, a “democratic metal” that could be used in numerous applications of all types. The classical Greek and Roman civilizations (600 BCE–400 CE) didn't contribute significant advances in metallurgical techniques. They extended the use of iron, as much for weapons as for tools used by artisans and farmers. The expansion of iron metallurgy and its dominance as a useful metal did not, however, pose an obstacle to the development of the nonferrous metals. Gold, silver, and bronze, besides being used for ornamental and household equipment purposes, were linked to the production of currency, whose growing use was related to the expansion of trade. Brass, an alloy of copper and zinc known prior to the classic period, began to be widely used for coinage by the Roman Empire. Lead, initially a byproduct of silver production, was extracted and removed from silver by cupellation, and was used extensively by the Romans for water pipes and cisterns. Mercury, obtained by means of distillation of cinnabar and used in Greek and Roman times for gilding, was linked to the recovery and refining of a variety of metals, especially gold and silver, through various techniques of amalgamation.

After the fall of the Roman Empire, the territories of western Europe entered a long period of economic

decline and probable technological stagnation, including stagnation in metallurgical production. Starting from the ninth century CE, however, manufactured metals were again incorporated into daily life in European societies. Nonferrous metallurgy was concentrated around the rich mines of central and Eastern Europe, with a heavy concentration, in particular, of German miners and metallurgists. Complex systems were introduced for the extraction of minerals in deeper and deeper exploitation, especially minerals with silver content. However, the foundry techniques continued to be very similar to those used in antiquity.

It was in iron metallurgy where progress was more significant. The introduction of hydraulic power to move bellows and hammers (in the twelfth and thirteenth centuries), together with the gradual increase in the size of furnaces, allowed a notable increase in the scale of production, higher yields, and a reduction in costs. The fifteenth century saw the spread of the indirect process based on the new technology of the blast furnace and the production of cast iron. Thanks to the achievement of higher temperatures, the new furnaces allowed one to obtain liquid metal, which made possible the use of molds for the production of very diverse items, but especially for the foundry of cannons and other smaller artillery pieces, which would have definitive social and political consequences. Nevertheless, most of the cast iron coming from blast furnaces was still destined for conversion into wrought iron.

Advances in Metallurgy During the Renaissance

In spite of progress in the iron and steel industry in Europe, during the Middle Ages the East remained far ahead in this field technologically. The steel coming from India and Japan allowed the manufacture of sword blades that were highly superior to those used in Europe. In China the production of cast iron, known from c. 200 BCE, grew at an extraordinary rate. By the thirteenth century a large industrial complex linked to the state and to military demand

had incorporated the foundry, using coal and the hydraulic wheel to work piston bellows, which were much more efficient than the systems used in Europe. Starting from the fifteenth century, however, Chinese metallurgy (like other important technological areas where China had been ahead of the West) was clearly stagnating, while Europe entered a new stage of technological progress and world hegemony.

In the Europe of the Renaissance, metal articles became more and more common in daily life. Demographic growth, the expansion of productive activity and trade, urban development, oceanic travel, and overseas discoveries and colonial expansion required a growing consumption of metals. Iron continued to be the metal used most frequently and extensively. The dimensions and productive capacity of blast furnaces increased gradually, and it was possible to mechanize the manufacture of iron by means of slitting mills that worked hydraulically.

After iron, the most widely used metal continued to be copper, along with its main alloys (bronze and brass). Currency necessities and the demand for bronze artillery required a growing consumption of this metal. Japan was the main producer of copper in Asia and, from about the middle of the seventeenth century, it exported significant quantities to Europe. In Europe, the copper industry was developed initially in Hungary and central Europe, in Sweden toward the end of the sixteenth century, and in England toward the end of the seventeenth. The demand for precious metals remained linked mainly to the currency demand of a more and more commercialized world economy. Production expanded due to the discovery and exploitation of the mines of Spain's colonies in the New World (Mexico, Peru), the main source of the world supply of silver from the sixteenth century onwards.

Although production techniques for nonferrous metals evolved more slowly, during the Renaissance new procedures were introduced, improving on some that were already well known. Among these innovations, reverberatory furnaces came into widespread use, coal was introduced as a fuel in certain cases, and welding techniques were improved. Most silver

was extracted from lead and copper ores by means of new cupellation and amalgamation procedures. In Saxony a new and complex method was introduced for obtaining silver by means of liquation of copper ores. In the New World, the Spanish conquest allowed the acquisition of large quantities of gold and silver that had been accumulated by the indigenous populations, primarily from native metals. From about the middle of the sixteenth century, when the potential for sacking and spoliation had been exhausted, active metallurgical production was implemented, based on an amalgamation system known as the “patio process,” which allowed extraordinary growth in the production and trade of silver.

At this point, migration and the growing mobility of a specialized labor force were the main vehicles of diffusion for the new techniques, as had happened earlier with miners and metallurgists of German origin, who formed the most active nucleus of European metallurgy. On the other hand, the publication of various treatises that described with great detail and practicality the well-known techniques of the moment introduced a new element into progress in metallurgy. The works, published by V. Biringuccio (1549), G. Bauer (1556), and L. Ercker (1574), synthesized the main metallurgical procedures, creating an easily transferable, and therefore cumulative, body of knowledge.

The first Industrial Revolution (1760–1830) precipitated a new technological leap in iron production and, to a lesser degree, in the other branches of metallurgy. By the end of the eighteenth century, thanks to the gradual adoption of coal as a fuel, to the steam engine as a mechanism of propulsion, and to the puddling furnace in combination with the rolling mill, the English iron and steel industry had been able to eliminate the main technological obstacles that had slowed the growth of the sector. Iron, produced in large quantities and at lower costs, could be used in a massive way in the key sectors of the new industrial economy (such as railroad, shipbuilding, and mechanical industry) substituting for wood and other traditional materials. Production of nonferrous-metals grew more slowly and without significant technical

changes, other than some exceptions like the distillation systems applied to the production of zinc after 1738. However the growing importance of scientific investigation and applied chemistry allowed for the discovery and isolation of new metals, such as cobalt, nickel, manganese, and tungsten, among others.

Contemporary Metallurgy from 1850

The technical advances of the second Industrial Revolution would make the hegemony of iron metallurgy even greater. Where the British discoveries of the eighteenth century had allowed for the industrialization of cast and wrought iron production, in the second half of the nineteenth century decisive technical changes would be achieved in steel industry. By means of the Bessemer (1856), Siemens-Martin

A section of the bag house from J. L. Bray, *The Principles of Metallurgy*, New York: Ginn & Co., 1929. The bags filtered lead fumes and fine dust after smelting. Library of Congress.

(1857–1864), and Thomas-Gilchrist (1878) converters, it was possible to produce steel in large quantities at prices far below the previous ones. Thus steel could be used, in place of wrought iron and other materials, in a much more extensive way in all types of applications. Thanks to its hardness and elasticity it could be incorporated into the building, railroad, shipbuilding, and mechanical industries, among other sectors, contributing in a decisive way to the advancement of industrial societies.

The consumption of nonferrous metals was also affected by advances in the industry. New products and new demand sectors—such as those linked to the modern armaments industry, electrification, the beginnings of the automotive and the aeronautics sectors, and certain goods produced for domestic consumption—increased the general demand for metals and alloys with more and more precise technical requirements. The new colonialism, the internationalization of the economy, and the development of modern means of transport led to the discovery of new ore deposits and the extension of mining throughout the world. In certain cases, the procedures used in the iron and steel industry could be applied with success to other metals. But limitations imposed by traditional metallurgy were overcome with the development of new methods of electrometallurgy. These consisted of applying the potential of electric power as a thermal agent and incorporating electrolytic methods in the extraction and refined processes. The new procedures made it possible to improve the purity of the metals obtained and to produce new metals and alloys industrially.

Although there had already been advances in industrial chemistry at the beginning of the nineteenth century, it was not possible to develop the full potential of electrometallurgy until the availability of abundant and cheap electricity. In fact, copper, whose purity was a decisive characteristic for use as an electrical conductor, was the first industrially refined metal obtained by means of electrolysis (1865), which contributed in a decisive way to the growth of the electric industry. Aluminum, magnesium, special steels, and other very diverse alloys could be

developed commercially thanks to the technical and economical possibilities of electrometallurgy. In addition, electric furnaces have provided the industry with greater flexibility of location and have reduced pollution emissions considerably.

The development of contemporary metallurgy has been associated with important advances in the administration and the organization of the industry. The necessity of integrating different production processes in a single factory, the high cost of equipment, and the concentration of production and markets have transformed the structure of the industry and paved the way for the great modern firms and for mass production, especially in the iron and steel industry. Although in some cases experimentation and practice continue to be important, technological development in contemporary metallurgy depends more and more on advances in science and investigation.

During the twentieth century the extraction and treatment of metals continued to evolve without interruption, and at an increasingly rapid pace. The progress of contemporary metallurgy has been based on new industries and demand sectors, such as atomic engineering, electronics, telecommunications, and the aerospace and military industries. Improvement in the quality of the final products, reductions in cost, the search for new alloys, and industrial production of new metals like titanium, beryllium, zirconium, and silicon have required the introduction of constant technical changes, as much in the production and finishing processes as in methods of analysis and control of the production process. Some of the technological alternatives developed in the new metallurgy of the twentieth century are: continuous casting and the Basic Oxygen Steel process in the steelmaking industry, hydrometallurgy (aqueous processing of metals) for the treatment of precious metals and minerals of high value (uranium, nickel, cobalt), the use of powder metallurgy to obtain certain structural parts for industrial use, and special alloys of mixed constitution (with metallic and non-metallic elements).

The complexity and speed of technological change in advanced societies make it impossible to foresee future tendencies in metallurgy. The most recent

progress in the science and engineering of materials is allowing the constant development of new materials and processes. Although in some cases new plastics, ceramics, and hybrid materials may compete with and displace metals in certain applications, the development of metallurgical engineering in the current technological environment of cross-disciplinary investigation will continue to constitute a decisive element in the technological progress and industrial systems of the future.

Migration—Overview

Early humans spanned the globe in ways that are still unclear to us, but we do know migration has been a constant feature of human history. Colonization, trade, military action, and slavery became important drivers of migration with the rise of agriculture and settled states. In the last two centuries, long-distance labor migration has grown enormously, giving rise to laws that attempt to regulate human mobility.

Humans are a mobile species. The spread of *Homo erectus* out of eastern Africa from 4 to 1 million years ago, and the subsequent spread of *Homo sapiens* that began within Africa by at least 100,000 BP (before the present) and departed Africa by 60,000 BP are the clearest examples of this. Our ability to relocate and adapt to new surroundings is inseparable from our rise as one of the dominant life forms on the planet. Our knowledge of these early migrations is sketchy. It relies on painstaking research in archaeology, linguistics, and genetics. Many of the results are still tentative, complicated by the fact that languages, genes, and material culture may or may not have moved together.

Early Humans

Scholars offer several theories to explain human migration from Africa. Early accounts of the journey out of Africa proposed that humans followed large herds of grazing animals directly overland into Europe and across Central Asia. But the fact that humans arrived in New Guinea and Australia about 50,000 BP suggests another movement across the tropical belt, perhaps hugging the coastline with the help of rafts. This

hypothesis can be further investigated with underwater archaeology, because sea levels have risen and most of what was the coastline of 50,000 years ago is now underwater. Similarly, the only clear archaeological evidence to date the migrations into the Americas is from 14,000 BP, found in what is now Chile, about as far distant as can be from the land bridge between Siberia and Alaska that is presumed to be the route by which humans arrived in the Americas. Most scholars hesitate to date the arrival in the Americas much earlier than this material evidence. But some linguists and geneticists have suggested that the migrations may have begun as long as 35,000 years ago. Whatever the earliest date of arrival, it seems reasonable to suggest that migrants arrived in the Americas via several waves rather than just one, culminating in the most recent waves across the Atlantic from Africa and Europe over the past 500 years, and from Asia over the past 150 years.

As our knowledge grows, it appears increasingly likely that early migrations were not just a single wave that slowly spread across the Earth, but a complex pattern of multiple directions, reversals, and replacements. This is most apparent when we look at scattered pockets of isolated groups around the world, whose languages have no common origins with any of their contemporary or known historical neighbors. Examples include the Basques in northern Spain, the Yeniseians in northeast Siberia, and the peoples speaking North Caucasian and Kartvelian languages between the Black and Caspian seas. These groups are likely the remnants of early populations that resided in these areas before the arrival of newer migrants anywhere between 35,000 to 10,000 years ago. Unsurprisingly, little is known

This romanticized drawing from a book of Polynesian myths shows men setting off in an outrigger canoe. Peoples who settled the Pacific Islands likely traveled in such canoes.

about the origins of these earliest populations. They may have moved across Eurasia directly from Africa. They may have radiated from a hearth of early humanity in the Caucasian mountains and eastern Anatolia. Some scholars have even speculated that the isolated languages they spoke are part of the Dene-Caucasian language group, which includes Chinese and Tibetan. This would push the origins of their languages to the Southeast Asian highlands, followed by a subsequent dispersal that moved north across Eurasia. Similarly, the later migrants that displaced these earlier populations might not have come directly from Africa but from the area that is now North Korea and Manchuria, where the Eurasiatic languages may have originated as many as 35,000 years ago. With the help of technologies such as skin rafts, Eurasiatic speakers migrated across the northern latitudes all the way from northern Canada to Ireland. These migrants included Indo-European, a

sub-group that eventually generated yet more waves of global migration that often displaced the speakers of Eurasiatic and Indo-European languages who had arrived earlier.

The causes and organization of those early movements is also unclear. Contemporary hunter-gatherers live itinerant lifestyles, but are largely confined to specific and relatively familiar territories, in part because of the pressures of the settled states around them. In conditions of relatively unpopulated frontiers, what would lead humans to spread out to new lands and learn the new technologies necessary for survival in those lands? Did entire communities move in search of food, space, or a spiritually benevolent environment? Or did isolated individuals or break-off groups leave their home community and eventually create new communities on their own or through bonding with other such individuals? If so, were such individuals compelled to leave their homes, or were they the young adults in search of wealth and adventure that have predominated among migrants during periods of written history? Did they, as is the case with many more recent migrants, originally intend to return to their home communities only to find this goal impossible to achieve? Did these new communities grow through the help of migration from other communities through marriage, capture, and voluntary movement? And, when peoples moved into places that were already inhabited, as must be assumed under models of multiple waves of migration, did they displace, live next to, merge with, or become subsumed into the preexisting communities? Presumably, specific mixes of all these possibilities happened at different times and places.

Domestication, States, and Migration

The domestication of plants and animals over the past 13,000 years has changed the patterns of human mobility. The change was not sudden: itinerant hunter-gatherer groups still exist to this day, and many peoples have mixed residence in agricultural villages with foraging and hunting excursions that could last anywhere from days to months. But by

3000 BCE new regimes of human mobility had clearly emerged. Animal husbandry and agriculture were each associated with their own forms of movement. Animal domestication was associated with pastoral nomadism in many parts of the world, in which small groups followed and led flocks to grazing grounds along seasonal circuits. Agriculture, on the other hand, increasingly tied people to single locales. But it also facilitated the rise of large states, and new forms of mobility through military action, colonization, trade, and labor migration.

The spread of these technologies was often associated with the expansion of linguistic groups, even if not necessarily with all of the speakers of those languages. The spread of Indo-European languages during the three millennia after 3000 BCE from their homeland north of the Black Sea across a region spanning from Ireland to northern India was often linked to horse domestication, and possibly to the chariot. Bantu languages started in what is now Nigeria and spread to the southern and eastern parts of Africa from 3000 BCE to 500 CE, often in association with new agricultural technologies. Austronesian languages began their spread from southeastern China through much of maritime Southeast Asia in 3000 BCE along with technologies such as rice agriculture, the stilt house, and pottery. By the time these migrations reached their farthest destinations in Hawaii, New Zealand, and Madagascar less than a thousand years ago, however, many of these technologies had been lost, with the notable exception of their formidable maritime skills based in the outrigger canoe. In all of these cases except the Polynesian islands, it remains uncertain to what extent the mobility was one of expansion into relatively unsettled areas, the conquest and replacement of previous populations, or of some mix of peoples, technologies, and languages moving across existing communities.

These technologies also facilitated the rise of military formations. The effects of the military on mobility could take many forms: the recruitment of soldiers, prisoners, and laborers for army service and public works; the movement and resettlement of administrators, craftsmen, and occupying armies to conquered

lands; the establishment of military colonies and frontier garrisons; the creation of refugees; the forcible transfer of villages and populations; and the transport of prisoners to provide public spectacle in important population centers. Some of the more well-known migrations of the past 2,000 years are associated with military conquest and colonization. These include the spread of the Greeks as far as Afghanistan behind the conquests of Alexander in the fourth century BCE; the Arab expansion of the seventh and eighth centuries that brought Islam in its wake from Spain to the borders of China; the Viking conquests in Europe from the ninth to eleventh centuries, and the Mongol conquests of much of Asia in the thirteenth century. Although in all of these cases (except perhaps the Mongols) the conquerors left an enormous cultural and linguistic legacy, but were not necessarily the majority of migrants themselves. The bulk of the people who moved may actually have been soldiers, craftsmen, traders, and refugees of other ethnicities who were compelled to move or who took advantage of opportunities in the newly expanded political spaces. The historical record often overlooks these migrations of the conquered and conscripted, although the Jewish exiles to Egypt and to Babylon, and their later global Diaspora from these destinations and from their homeland, are perhaps the most well-known of all migrations.

The rise of states, empires, and nomadic peoples also facilitated the rise of mobility for the sake of long-distance trade. Powerful states were able to regulate the trade routes, create an elite with a demand for luxury goods, and mobilize resources necessary for long trading expeditions. The skills and knowledge of nomadic peoples in Central Asia, Arabia, and the Sahara in navigating the vast expanses were a crucial part of these trade routes. Long-distance trade also led to the creation of trade diasporas, peoples linked through bonds of family, ethnicity, and common commercial interest who managed the purchasing, financing, transportation, and retailing of goods across these distances. The spread of major world religions and exchange of artistic forms also followed these routes. At the same time, growing commerce

A great emigration necessarily implies unhappiness of some kind or other in the country that is deserted. • **Thomas Malthus (1766–1834)**

and trade encouraged short-distance migration, especially to growing cities, periodic markets, and for seasonal agricultural labor. The transportation routes themselves became a major cause of migration, requiring the labor of numerous porters, animal drivers, guides, guards, and sailors. For more skilled professions, sometimes entire villages or itinerant castes and groups would specialize in the training of certain crafts such as stonework, acting, or construction, and travel the circuits from markets to manors to practice their crafts.

States could also fear unregulated mobility. The gradual suppression of nomadic peoples from 1500 until the twenty-first century is one example of this. But states also tried to manage the mobility of settled people within their borders. This rarely happened in the form of immigration laws and border control as we know now. Rather, states were more concerned to control domestic mobility and stop exit, thinking that a large population tied to the farms and fixed sites of craft production, and easily located for the sake of military service, was a source of wealth and power. In practical terms, individual towns and villages actually devised and enforced these regulations more than states. The local communities knew who was and was not an outsider, and could more effectively administer discriminatory taxes, residence permits, vagrancy and poor laws, quarantines, naturalization procedures and other regulations designed to differentiate subjects from aliens, and the different kinds of rights that were distributed to different groups.

These processes of power and mobility converged in the rise of slavery into one of the major forms of human mobility until the late nineteenth century. The rise of military formations that could be used for raids and capture, the wealth of agricultural states, the formation of settled agricultural families, and the rise of property laws and long-distance markets all facilitated the rise of slavery around the world as a means of both coercing and financing human mobility. The forms of slavery varied enormously, from de facto adoption into families to brutal labor exploitation on plantations and mines. But the relationship of slavery, markets, military, and states was a firm one.

All of these forms of mobility converged into one of the greatest migrations of human history, the conquest and repopulation of the Americas, which also provide a convenient illustration of the varied effects of migration. The movement of over 10 million African slaves from the sixteenth to nineteenth centuries was the greatest human relocation to date. The genetic impact of these migrants on the American population is undeniable, yet their linguistic and cultural impact is scattered and diffuse. The cultural and linguistic impact of the 3 million Europeans who arrived in the Americas before the 1820s is much more pronounced. But this, too, was subject to variations. In much of what is now Latin America, European genes are mixed with indigenous American and African through *mestizaje*. And, while European language and culture clearly dominates, African and indigenous American influences are prominent in many regions. Total migration before 1820 to North America and the southern cone of Argentina was much less than to other parts of the Americas. Yet the destruction of the native population was much more complete and the great majority of culture, language, and genes have come from Europe. This, of course, was largely an effect of the new waves of mass migration that began in the nineteenth century, a subject addressed in the following section.

Mass Migration from 1840 to 1940

Global migration boomed after the 1840s. This is especially true of long-distance migration facilitated by the growth in trains, steamships, airplanes, and other inexpensive and rapid transportation technologies. But shorter distance migration also grew, in conjunction with unparalleled urbanization and commercialization. These developments were inseparable from industrialization, the expansion of global markets and the concurrent massification of production, mobility, and consumption. People were drawn to jobs in factories, plantations, mines, and cities, and to distant frontiers where they provided food and resources to supply the growing industrial centers. The fields of Siberia and North America, the

This panel of cartoons expressing American anti-immigration sentiments of the late 1800s shows Uncle Sam being consumed by Irish and Chinese immigrants.

mines of South Africa and Manchuria, the rice paddies of Thailand and Hawaii, the rubber plantations of Malaysia and the Amazon, the factories of Chicago and Manchester, the canals of Panama and Suez, the entrepôts of Singapore and Shanghai, the service jobs of New York and Bombay, and the oil fields of Qatar and Venezuela have all drawn migrants as key nodes in an expanding global economy.

Much of this mobility was the continuation and expansion of practices that had been going on for centuries: travel for trade and business, the colonization of agricultural lands, the movement of soldiers

and sailors, and the constant ebb and flow of forced and free labor to plantations, mines, factories, and domestic service both far and near. But the explosion in quantity was also a transformation in quality. These migrations were increasingly free, less linked to the military, and dominated by labor migrants looking for work. Many migrants also intended to make temporary journeys to earn money and resources that could be used to support their families back home, although these intentions often changed with time. Over the course of the twentieth century, migrations were also increasingly shaped by management and

purification of national populations in the form of border controls and refugee movements.

After the 1840s, it becomes easier to specify the directions and quantities of migration. Long-distance movement increased more rapidly than world population from the 1840s to 1930, with only brief fluctuations due to the depressions from the 1870s to 1890s and World War I (1914–1918). It averaged 3.2 million migrants a year from 1906 to 1914, with transatlantic migration reaching a spectacular peak of over 2.1 million in 1913. After World War I, migration hit new peaks of 3.3 million a year in the late 1920s, with migration to Southeast Asia peaking at 1.25 million in 1927, and migration to northern Asia peaking at 1.5 million in 1929. The Great Depression put a stop to much migration, with the significant exception of the command economies of Japan and the Soviet Union, where coercion, government promotion, and relatively strong economies produced rates of up to 1.8 million migrants a year into northern Asia in the late 1930s. Long-distance migration did not again regain these per annum rates in comparison to world population until the 1990s.

Migrants who traveled by ship before World War II were counted at ports and in ships' logs, thus providing excellent data for estimates of transoceanic migration. Government frontier settlement programs such as the movement of Russians to Siberia, have also left behind some excellent data. Such estimates usually obscure return and repeat voyages. But they nonetheless allow for reasonable estimates of major long-distance and trans-oceanic migration flows.

At least 170 million long-distance (transoceanic and trans-Siberian) voyages took place from 1840 to 1940. These migrations can be divided into three main systems: 1) 55–58 million migrants from Europe and the Middle East to the Americas; 2) 48–52 million Indians and South Chinese to Southeast Asia and areas bordering the Indian Ocean; and 3) 46–51 million North Chinese, Russians, Koreans and Japanese into central and northern Asia, especially to Manchuria and the southern portions of Siberia. The majority of long-distance migration from 1840 to 1940 can be divided into three main systems. In

addition, about 2.5 million East Asians and Indians moved to the Americas, about 8 million Europeans moved to Africa, Asia, and Australia.

Over 65 percent of the transatlantic migrants went to the United States, with the bulk of the remainder divided between Canada, Argentina (which had the largest proportion of foreign-born residents), Brazil, and, to a lesser extent, Cuba. Over half of the emigration before the 1870s was from the British Isles, with much of the remainder from northwest Europe. After the 1880s, regions of intensive emigration spread south and east as far as Portugal, Russia, and Syria. Up to 2.5 million migrants from Southeast Asia also traveled to the Americas, mostly to the frontiers of western North America or the plantations of the Caribbean, Peru, and Brazil. Half of this migration took place before 1885, after which the decline of indentured labor recruitment and the rise of anti-Asian immigration laws began to take effect.

Migration to Southeast Asia and lands around the Indian Ocean and South Pacific consisted of over 29 million Indians and over 19 million Chinese, with much smaller numbers of Japanese, Europeans, and western Asians. Most migration from India was to colonies throughout the British Empire. Less than 10 percent of this migration was indentured, although much of it was undertaken with assistance from colonial authorities, or under some form of debt obligation under *kangani* labor recruitment systems. Over 2 million Indians also migrated as merchants or other travelers not intending to work as laborers. Migration expanded with the increasing restriction of indenture contracts in India after 1908 and the abolishment of indenture in 1920. Nearly 4 million Indians traveled to Malaysia, over 8 million to Ceylon (now Sri Lanka), over 15 million to Burma (now Myanmar), and about a million to Africa, other parts of Southeast Asia, and islands throughout the Indian and Pacific oceans.

The vast majority of Chinese migrants came from the southern provinces of Guangdong and Fujian. Fewer than three-quarters of a million of them signed indenture contracts with European employers,

including a quarter million to Latin America and the Caribbean before 1874, a quarter million to Sumatra from the 1880s to the 1910s, and a smaller number to mines, plantations, and islands scattered throughout the Pacific and Indian oceans. Many more Chinese worked for Chinese employers under various forms of contract and debt obligation, wage labor, and profit sharing. Up to 11 million Chinese traveled from China to the Straits Settlements, although more than a third of these transshipped to the Dutch Indies, Borneo, Burma, and places farther west. Nearly 4 million traveled directly from China to Thailand, between 2 and 3 million to French Indochina, over a million to the Dutch Indies (for a total of over 4 million if transshipments from Singapore are included), fewer than a million to the Philippines, and over half a million to Australia, New Zealand, Hawaii, and other islands in the Pacific and Indian oceans.

In the north of Asia, the Qing dynasty (1644–1911/12) government's gradual relaxation of restrictions against movement into Manchuria after 1860 and the emancipation of serfs in Russia in 1861 set the stage for more massive migration. Both governments actively encouraged settlement with homesteading policies in the 1880s, each partly inspired by the desire to forestall territorial encroachment by the other. Railroad construction in the 1890s further strengthened the migrant flows. Between 28 million and 33 million Chinese migrated into Manchuria and eastern

Siberia, along with nearly 2 million Koreans, and more than a half million Japanese. Another two and a half million Koreans migrated to Japan, especially in the 1930s. At least 13 million Russians moved into Central Asia and Siberia over this period. In addition, up to a million northern Chinese, Koreans, and Japanese migrated to a diverse range of destinations, including much of the Americas, Hawaii, Southeast Asia, South Africa, and Europe.

These long-distance movements created a significant shift in the distribution of the world's population. All three major destination regions experienced massive population growth, with their populations increasing by factors of 4 to 5.5 from 1850 to 1950. (See table 1.) These rates were over twice that for world population as a whole. Growth rates in the sending regions were lower than world population growth, and less than half the rates in the receiving regions. Taken together, the three main destination regions accounted for 10 percent of the world's population in 1850 and 24 percent in 1950.

Emigration rates were uneven within particular regions, with some villages or counties sending numerous migrants while others send hardly any at all. Nonetheless, average emigration rates in all of these systems are broadly comparable. At first glance 19 million overseas emigrants from China or 29 million from India seems negligible compared to the several millions from much smaller countries like Italy,

Table 1.
World Population Growth by Regions from 1850 to 1950 (in millions)

	RECEIVING		
	1850 Population	1950 Population	Average annual growth
Americas	59	325	1.72 %
North Asia	22	104	1.5 7%
SE Asia	42	177	1.45 %
	SENDING		
	1850 Population	1950 Population	Average annual growth
Europe	265	515	0.67 %
South Asia	230	445	0.66 %
China	420	520	0.21 %
World	1200	2500	0.74 %

McEvedy, C., & Jones R., (1978). *Atlas of world population history*. London: Penguin.

Norway, Ireland, and England. But if we look at regions of comparable size, the rates are very similar. Some of the peak recorded emigration rates ever were an annual average of 22 emigrants per 1,000 population in Ireland during the famine of 1845 to 1855, or 18 per 1,000 from Iceland in the 1880s. Some South Pacific and Caribbean islands probably experienced similar rates. More typical rates in periods of high overseas emigration are 10.8 per 1,000 from Italy, 8.3 per 1,000 from Norway, and 7 per 1,000 from Ireland in the first decade of the twentieth century. In comparison, the annual average overseas emigration rate from Guangdong Province in the south of China, which had an area slightly larger and population slightly smaller than Italy, was at least 9.6 per 1,000 in the peak years of the 1920s. Hebei and Shandong provinces (sources of migration to Manchuria) had a rate of 10 per 1,000 during that same decade.

These three systems were still only the tip of the iceberg. Many migrants also moved through Africa and western Asia, and within the main sending and receiving regions. The majority of global migration was probably to nearby cities, towns, and agricultural areas, often on a temporary basis. This migration is more difficult to count, but general patterns can be identified.

Africa experienced net immigration, but in much smaller numbers than other main destinations and from a wider variety of origins. The immigrants included over 3 million French and Italians into North Africa and up to a million other Europeans, Syrians, Lebanese, Arabs, Indians, and Chinese throughout the continent. The end of the transatlantic slave trade led to increased movement of slaves into the western Sudan, Middle East, and areas bordering the Indian Ocean in the late nineteenth century. Labor migration to plantations and mines in southern and central Africa increased through the late nineteenth and twentieth centuries, as did movement to agricultural areas and coastal cities in western and eastern Africa. Millions of people took part in these movements, some of whom were coerced and many of whom went to work for European enterprises, but many of whom also

found independent occupations. Projects such as the Suez Canal and development of an infrastructure for cotton cultivation in Egypt attracted large amounts of local migration, while Lebanon and Syria experienced some of the highest overseas emigration rates in the world. In a different type of migration, over 3 million people took part in the pilgrimage to Mecca from 1879 to 1938.

Western Asia and eastern Europe were areas of massive migration caused by violence and politics, a harbinger of the kinds of migration that would become increasingly prominent over the twentieth century. The dissolution of the Ottoman Empire and wars with Russia led to an exchange of 4 to 6 million people, with Muslims moving south from the Balkans, Greece, and Russia into Turkey, and Christians moving in the other direction. Around a million Armenians were expelled from Turkey to points around the world, and nearly 400,000 Jews moved to Palestine in the early twentieth century. The massive movement of refugees would extend to other parts of Europe in the wake of World War I and the Russian Revolution, including the movement of 3 million Russians, Poles, and Germans out of the Soviet Union.

Migration also took place within the receiving regions of the long-distance systems. The transatlantic migrations could be extended to include the 13 million people who moved to the western frontiers of North America. This process also spurred the relocation of great numbers of Native Americans, and the migration of over 2.5 million Mexicans to the agricultural areas of the southwestern United States in the early twentieth century. The industrial centers of the northeastern United States also attracted over 2.5 million Canadians, and then over a million African Americans and Mexicans in the early twentieth century. In other parts of the Americas, great numbers of Andean peoples moved to coastal plantations and cities, and over 300,000 Caribbean people migrated to plantations in Central America and Cuba, to the Panama Canal Zone, and the United States. In Southeast Asia and the South Pacific, up to 500,000 Javanese traveled to plantations in Sumatra and the

The Vila Canoas favela in Rio de Janeiro. Favelas, settlements that originated illegally in the early 1900s, attract migrants looking for employment in Brazilian cities. The government now works to provide basic human services to these areas.

Southeast Asian mainland, and over 400,000 Melanesians and Micronesians worked on plantations and as seamen throughout the region.

In Europe, migrants from Ireland traveled to England for work, and those from eastern and southern Europe to industrial areas in northern Europe, especially France and Germany. In Russia, migrants moved into the growing cities and southern agricultural areas. Within India they moved to tea plantations in the south and northeast, to the mines and textile-producing regions of Bengal, and to newly irrigated lands and urban areas throughout the subcontinent. In China, they migrated to growing coastal cities, to areas of the Yangzi (Chang) River basin left underpopulated by the devastating casualties of the Taiping Rebellion, and to borderland areas of the northwest and southwest, including overland migration to Burma.

These massive flows led to a backlash in the form of stricter migration laws. The middle of the nineteenth century was an unparalleled era of free movement.

By the 1860s, most exit controls and the local laws regulating domestic movement had been dismantled. By the 1880s, however, new regulations in the form of medical inspections and laws to keep Asian migrants out of white settler nations were in force. By the 1920s, these laws had expanded into quotas, multiple categories for admissible and nonadmissible migrants, and even a resurgence of exit controls, especially by Communist nations. Many people began to assume that a nation could not be sovereign and independent without control of its borders against immigration. The same forces and technologies that led to the boom in global mobility also made it possible to increasingly control that mobility and to make somebody “illegal” merely by virtue of moving without documents.

Migration Since World War II

International migration remained relatively low in the decades immediately following World War II, with

the exception of massive refugee flows in Europe and south Asia that resulted from the new European political map after World War II, the creation of Israel, and the partition of India. Refugees have remained an important source of migration to this day, especially in Africa, Central America, and Southeast Asia. Rural-to-urban migration also grew increasingly important in Asian, African, and Latin American countries over the second half of the twentieth century. International migration to industrialized countries expanded steadily after the 1960s, due to immigration laws that provided for guest workers, family reunification, and migration from ex-colonies. Major flows have included migrants from western and southern Asia and northern Africa to Europe, from Latin America and east Asia to North America, and from Asia to Australia. Migration to expanding economies in Japan, Southeast Asia, Argentina, South Africa, and especially to the oil-rich areas of the Middle East has also grown since the 1970s.

Due to the great diversity of administrative categories used to count migrants, it is more difficult to estimate global migration since World War II than for the previous century. A crude estimate of annual migration flows in the 1990s could start with yearly figures of 1.2 million legal migrants to the European Union and 400 to 500,000 irregular migrants. Migration to the United States averaged 860,000 legal migrants a year and perhaps another 300,000 illegals (still less than the highest numbers of 1912–1913). Migration into Canada, Australia, and New Zealand accounted for another 300,000 each. Over a million migrants traveled each year to the Persian Gulf states and Israel. Over half a million asylum applications were also made each year around the world, often not counted in migration statistics. Other major destinations include Argentina, Venezuela, South Africa, and Japan, and large flows moved between countries in Africa, Southeast Asia, and the ex-Soviet republics. A generous estimate of 2 to 3 million migrants a year for these other destinations would constitute an annual migration of 6.5 to 7.5 million a year. A hypothetical return rate of 40 to 45 percent could account for the

increase of 40 million migrants found in migrant stock estimates from 1990 to 2000. Most evidence points to migration rates remaining steady in the first decade of the twenty-first century.

A comparison of this number with the peak migrations of the early twentieth century shows absolute numbers that are up to three times higher than earlier migrations, but are quite similar as a proportion of world population. A total of 80 million migrants in the 1990s would account for 1.5 percent of world population, while the 32 million migrants from 1906 to 1915 accounted for 1.8 percent of world population. It seems likely that the impact of long-distance migration in these two periods is quite comparable. But this may not be the best measurement of global mobility. Some 700 million tourist entries were counted in 2000, up from 480 million in 1990 and 300 million in 1980, a growth that is several magnitudes of order larger than in the previous migration wave. While this movement may not generate significant shifts in the global population, it has had an enormous effect on the global economic, social, and cultural order.

Given the difficulty in counting mobility, most international organizations now prefer to count “migrant stock” in national censuses as a way to quantify the effects of migration. (See table 2.) This, too, is a very imperfect form of measurement, because some censuses count foreign birth, while others count only foreign residents who have not become citizens, and others merely note racial or ethnic distinctions. This system may also count people who have never moved all their lives, while international borders have moved around them. For example, the 20 million refugees created by the partition of India and Pakistan accounted for nearly 15 to 25 percent of the world “migrant stock” through the 1970s, even though south Asia is more important as a migrant producing than receiving region. Similarly, the break-up of the Soviet Union in the early 1990s led to a dramatic increase in the proportion of migrant stock in that area, as many people living in the newly created nations chose to retain the citizenship of Russia or neighboring nations.

Table 2.*Migrant Stock as Percentage of World Population (in millions)*

Year	Foreign-born population	Percentage of world population
1910	35.7	2.0
1930	42.9	2.1
1965	75.2	2.3
1975	84.5	2.1
1985	105.2	2.2
1990	155.5	2.9
2000	195.2	3.02
2005	213.9	3.1

Sources: International Labour Office 1936; United Nations Population Division 2008; United States Census Bureau 2010; Zlotnik, H. 1998.

About 20 percent of this migrant stock can be counted in the United States, and another 22 percent in western Europe. About 7 percent of all migrants are found in Canada, Australia, and Japan. Altogether, half of all international migrants are to be found in the developed countries, marking a shift away from earlier trends of migration toward frontier areas. Of the rest, about 12 percent are found in Eastern Europe, 7 percent in the Persian Gulf states, and the other 32 percent distributed among the other nations of the world. Although the United States ranks number 1 in total immigrants counted, only 12.8 percent of the population is migrants, placing it far behind small countries like Kuwait, Qatar, and the United Arab Emirates, in which 60–80 percent of the population are immigrants.

Other trends over the second half of the twentieth century include the rise of women and professional migrants. In the first wave of mass migration, men were the majority of migrants, with the exception of some flows like the Irish and the Jews. In the 1920s and especially the 1930s, women made up an increasing proportion. Now, about half of international migrants to most destinations are women. Similarly, migrants are no longer made up mostly of laborers and ex-peasants. Professionals have made up more than 20 percent of migrants into North America and Europe since the 1960s, and are a significant proportion of migrants into the oil kingdoms. Several immigrant groups in the United States, from Indians and Filipinos to Argentines and Nigerians have higher

educational levels and family incomes than the native-born white population. Immigration law preferences for the wealthy and educated play an important role in this stream, as does the lack of intellectually and financially attractive jobs in many poorer countries. Over time, however, migrant flows once dominated by educated professionals open the door for a rise in less-skilled migrants taking advantage of family reunification opportunities, and the proportions turn toward less-skilled migrants.

The expansion of migration laws and their continual proliferation of categories, have also shaped the quantities and directions of migration. In the twenty-first century it is almost impossible to talk of migration without simultaneously talking about status as tourists, immigrants, permanent residents, business travelers, holiday workers, guest workers, family reunification, investors, students, illegals, and the undocumented. The control of mobility is the most intensive space of systematic discrimination in the world today, where the accidents of birth and wealth determine who is free to move and who is a criminal by virtue of moving. In a world increasingly characterized by mobility, that mobility is impossible to understand apart from the controls and definitions imposed by states.

Migration, Asian

Asian peoples were among those participating in large-scale migrations, often over long distances, between 4000 BCE and 1000 CE. During the past several centuries millions of eastern and southern Asians relocated to become a visible and vital presence in the population of many nations and the world economy.

Human migration is a central theme in world history and can be traced back to prehistory. Some of the movements after 1500 CE are well known, such as the migration of millions of Europeans to the Americas, Oceania, and southern Africa and the transport of many enslaved Africans across the Atlantic. The less well-known migrations of Asian peoples also began early and continued down to modern times. During the past several centuries millions of eastern and southern Asians relocated temporarily or permanently, some to nearby countries, others to faraway lands, making these migrants and their descendants a visible and vital presence in the world economy and in the population of many nations.

The Long History of Asian Migration

Large-scale migration, often over long distances, has been a pronounced pattern for thousands of years. Various Asian peoples were among those on the move between 4000 BCE and 1000 CE. Chinese spread from northern into southern China. Mobile Central Asian pastoralists migrated frequently. Some of them moved into China, western Asia, or Europe. Various peoples from western and Central Asia crossed the high mountains into northwestern India, where they mixed with the existing populations. Many

Japanese descend from Koreans who crossed to the archipelago several millennia ago. Austronesians spread from Taiwan into the Philippines, Indonesia, and Malaysia. From there, some Austronesians, using advanced maritime technology and navigational skills, sailed east into the vast Pacific, settling remote islands and forming the Polynesian and Micronesian societies. The descendants of these Asians include the Hawaiian, Maori, Samoan, and Tahitian people. Other Austronesians sailed the other way, sojourning in East Africa and occupying the island of Madagascar. Thanks to migration, Austronesian languages are spoken today from the western Indian Ocean to the eastern Pacific. The ancestors of the closely related Thai and Lao peoples moved from southwestern China into Southeast Asia a millennium ago, eventually forming their own states.

In the eighteenth century, another large-scale migration of peoples from eastern and southern Asia began, mostly by sea to distant shores. The emergence of capitalism in Europe and the emergence of a truly world economy played a role. In a quest for resources and markets to be exploited, Western nations colonized most Asian, African, and American societies. The development of modern transportation networks, aided by the introduction of larger and faster ships and later by air travel, facilitated this movement. Some colonial powers looked to the densely populated Asian societies to provide a labor force for their plantations and mines. In more recent decades many Asians, some middle class, some refugees, and others impoverished workers seeking low-wage jobs, have migrated to Western nations legally or illegally.

Today perhaps 40–45 million Asians live outside, and often thousands of miles away from, their

ancestral homelands. Chinese and Indians account for the great majority of Asian migrants. Many settled in Southeast Asia, but the two groups also established large communities in the Americas, Pacific islands, Europe, and parts of Africa. Japanese, Koreans, Filipinos, and Indonesians moved to Pacific islands and the Americas. In the last thirty years of the twentieth century, several million Vietnamese, Laotians, and Cambodians fled war and repression for new homes elsewhere, particularly in North America. These varied diasporas of Asian peoples constitute one of the more important social and economic developments in modern world history.

Chinese Emigration

The Chinese accounted for some two-thirds of the long-distance Asian migration between 1750 and 1940. More than 30 million people of Chinese ancestry or ethnicity, often known as overseas Chinese, live outside of China, Taiwan, and Hong Kong today. Over 20 million of them reside in Southeast Asia. As a result, some 7 or 8 percent of all Southeast Asians have some Chinese ancestry. Three-quarters of Singapore's population is ethnically Chinese, as is a quarter

of the population of Brunei, a third of Malaysia's population, and thirteen percent of Thailand's. Three countries—Indonesia, Malaysia, and Thailand—each contain at least 4 million people of Chinese descent. More than a million ethnically Chinese people live in the United States. Several dozen nations or territories outside Southeast Asia also have sizeable Chinese communities. These include Japan, Canada, Mexico, Cuba, Jamaica, Trinidad and Tobago, Guyana, Surinam, Panama, Costa Rica, Peru, Brazil, the Society islands (including Tahiti), Fiji, Papua New Guinea, Australia, New Zealand, India, South Africa, Malagasy, Mauritius, Great Britain, the Netherlands, Germany, Portugal, France, and Russia. But most nations in the world have at least a few Chinese-run restaurants or other businesses, making the Chinese diaspora perhaps the world's most widespread.

This emigration has a long history. Chinese merchants have sailed to Southeast Asia to trade for several thousand years. By the fifteenth century Chinese trade networks linked Southeast Asian trading ports to the southeastern Chinese coast. Beginning in the later 1500s Chinese settlers became dominant in the commercial sector in several Western colonies in Southeast Asia, including the Spanish-ruled Philippines and Dutch-ruled Java. Between 1750 and 1850 many Chinese settled in Thailand, Malaya, and Indonesian islands such as Borneo to trade or mine for tin and gold, sometimes establishing their own self-governing communities. The present royal family of Thailand descends from an eighteenth-century Chinese immigrant.

During the later nineteenth and early twentieth centuries, wars with the Western nations and Japan, rebellions, corruption, population explosion, growing landlessness, and natural disasters in China prompted millions to emigrate, mostly to places where Western colonialism and capitalism were creating new economic opportunities. Some 90 percent of the emigrants came from two impoverished and overcrowded coastal provinces, Fujian and Guangdong, which were particularly hard-hit by Western military and economic intrusion. Between 1880 and 1920 several hundred thousand people a year left

Hula girls in their native costume. Indigenous Hawaiians are descended from Austronesians, ancestors also of the Maori, Samoan, and Tahitian peoples. New York Public Library.

from the ports of Hong Kong, Guangzhou (Canton), Xiamen (Amoy), and Shantou (Swatow) for foreign destinations.

Many were recruited into the notorious “coolie trade,” which operated from the 1820s into the 1920s. Under this system, desperate peasants become workers (known pejoratively as coolies) in far away places, especially Southeast Asia, various South Pacific and Indian Ocean islands, Hawaii, Australia, Peru, Cuba, California, and South Africa. In order to repay their passage, the Chinese signed contracts to work as plantation laborers, miners, or railroad builders for a fixed period of time, often five or ten years. The system invited exploitation in an alien environment, where the laborers who survived the difficult voyages in crowded ships faced discrimination and harsh working conditions.

Not all Chinese emigrated as part of this trade. Some paid their own fares, usually to join relatives in business enterprises. Most immigrants dreamed of returning to their native village wealthy, and some did. But many stayed overseas permanently, some because they had failed to achieve their dreams, others because they had established small businesses with their savings, marrying local women or bringing families

from China. But even those who settled abroad often sent money back to their home villages or invested in China. Today the overseas Chinese are an important source of capital for China.

Overseas Chinese Communities

Over time, the overseas Chinese were transformed from sojourners into settlers. Through enterprise, organization, and cooperation many Chinese in Southeast Asia became part of a prosperous, urban middle class that controlled retail trade. A few became fabulously wealthy businessmen or industrialists. Chinese commercial networks extended into the smallest towns. For example, many Chinese shops in small towns in Malaya and Borneo were linked through firms in larger towns to big companies in Singapore. Singapore, with a mostly Chinese population, became the major hub of Chinese economic and social networks in Southeast Asia, although Bangkok (Thailand), Jakarta (Indonesia), and Saigon (Cambodia) also played important roles. But some Chinese remained poor, eking out a living as commercial fishermen, smallholding rubber growers, or day laborers. For example, the men who pulled the rickshaws in the

Interior of a Chinese restaurant, New York City, early 1900s. Chinese have established large overseas communities in the Americas, Pacific Islands, Europe, and parts of Africa. New York Public Library.

steamy tropical heat of Singapore and Malaya faced a difficult life and often died young, sometimes from suicide.

Today the majority of Chinese in Southeast Asia, as well as in the South Pacific and Indian Ocean islands, the Caribbean, and Latin America, are engaged in commerce. The ethnic Chinese have constituted the most dynamic economic sector in Southeast Asia, with their money and initiative the basis for recent dynamic economic growth in Singapore, Malaysia, Thailand, Indonesia, and the Philippines. In North America and Europe many also opened businesses, often family-run restaurants, but many of their children gravitated to the professions or the high-technology industries. In the second half of the twentieth century many new emigrants fled Communism in China or lack of opportunity in Taiwan and Hong Kong for new lives in North America, Australia, Canada, or Europe. Most, especially the well educated, found success in their new homes, transforming the Chinese into one of the most affluent ethnic groups in these countries. But pockets of grinding poverty also remained, for example among the badly exploited immigrant workers in the small textile factories of crowded urban Chinatowns.

Many non-Chinese in Southeast Asia and the South Pacific resented the Chinese because of their enterprise, economic power, desire to preserve their language and culture, and their continuing ties to families or hometowns in China. Before the 1930s most Chinese in colonies such as Malaya and Cambodia were administered through their own leaders, usually powerful merchants, planters, or mine owners, perpetuating their separateness from local society. Conflict between descendents of Chinese emigrants and local people has been common in Indonesia, Malaysia, and the Philippines for several centuries, occasionally leading to anti-Chinese violence. Some governments have restricted Chinese political rights or curtailed economic activity. In the late 1970s many Chinese left or were expelled from Vietnam. Some of them joined a steady stream of Southeast Asian Chinese moving to North America or Oceania. But Chinese leaders run Singapore and have also played

an active role in Malaysian politics. Politicians of Chinese ancestry have led Thailand and the Philippines at various times, as well as Papua New Guinea, Guyana, and Surinam.

The Chinese have adapted to local environments in varied ways. Many assimilated over several generations. Some mixed local and Chinese customs, beliefs, and languages. These people formed distinct sub-groups such as the Peranakans of Java, the Straits Chinese of Malaya, and the Sino-Thai of Bangkok, who linked the Chinese and local peoples and moved between both worlds. But the majority of Chinese maintained their language, customs, religion, and separate identity. Many such people live in or near the large Chinatowns of cities such as Kuala Lumpur (Malaysia), Manila (Philippines), Sydney (Australia), Vancouver (Canada), San Francisco and New York (United States), Lima (Peru), and Liverpool (United Kingdom). Most Chinese emigrants spoke one of a half dozen quite different dialects. Wherever they have settled, the Chinese have organized their own schools, temples, business associations, and social organizations, fostering considerable cooperation and solidarity, which has helped sustain the Chinese communities in so many diverse environments.

Indian Emigration

Conditions in India also stimulated emigration during the nineteenth and early twentieth centuries, producing an overseas diaspora of nearly 10 million today, around a quarter of the emigrant Asian population. British colonization spurred population growth but also increasing poverty for many peasants, with no industrial revolution to absorb the excess people. As a result of these mounting problems, many millions of desperately poor, often landless, Indians, mostly Hindus but also some Muslims and Sikhs, were recruited to move to other lands. Many originated from South India; the Tamils of the southeastern coast became the largest Indian group in Southeast Asia and Sri Lanka. Others originated in North India.

The abolition of slavery in the Americas and the needs of sugar or rubber plantations in tropical

colonies created a market for indentured Indian labor. Governments in Sri Lanka, Malaya, Fiji, Mauritius, South Africa, and the Caribbean societies of Trinidad, Guyana, and Surinam recruited Indians in a system similar to the Chinese coolie trade. Other Indians built the railroads of British East Africa. Indian merchants, moneylenders, and laborers also flocked to British Burma (present-day Myanmar), Singapore, and East Africa. Some Indians settled on the Pacific coast of Canada and the United States. Between 1880 and 1930 around a quarter million people a year, both men and women, left India. The mortality rates were so high and the indenture terms so oppressive that critics considered the system another form of slavery. Later in the twentieth century several million South Asians moved to Britain, establishing growing communities in most industrial cities, emigrated to North America and Western Europe, or became merchants, service workers, and laborers in the Persian Gulf states.

Overseas Indian Communities

The resulting diaspora made Indians a recognizable group in countries around the world. Indian trade networks reach around the Indian Ocean and Pacific Rim, connecting the seaport of Aden in Yemen, Tanzania, Malagasy, and South Africa to Hong Kong, Japan, California, and British Columbia. The diaspora is reflected today in “little Indias” from Nairobi (Kenya) to Singapore to Trinidad. The great Indian nationalist leader Mohandas Gandhi (1869–1948) experimented with nonviolent resistance to oppressive power while working with the large Indian community around Durban, South Africa.

Today people of Indian ancestry account for a majority of the population in Mauritius, at least half the population of Trinidad, Guyana, Surinam, and Fiji, a fifth of the population of Sri Lanka, a tenth in Malaysia and Singapore, and 5 percent in Kenya and South Africa. They number some 1.5 million in Great Britain, around a million in the United States and Canada, and some 2 million in the Middle East. Sizeable South Asian populations, mostly involved

in commerce, also exist in several dozen African nations, most of Southeast Asia and Western Europe, many Caribbean islands, Australia, and New Zealand.

Indian experiences in the diaspora have varied. Some in Southeast Asia, Fiji, and the Caribbean have done well in business or the professions, while large numbers still labor on plantations, although often in conditions somewhat better than during colonial times. The majority in North America have become prosperous businessmen and professionals. Indian entrepreneurs and scientists are leaders in the high-technology sector. Indians in the United States enjoy the highest educational levels of all ethnic groups. In Great Britain many have achieved wealth as entrepreneurs and professionals, and others prosper as small shopkeepers. But some South Asians encounter discrimination and hostility in Great Britain and other Western nations.

Like the Chinese, overseas Indians have faced many challenges that have shaped their adaptation. Indians have been involved in bitter struggles for political power with the descendants of Africans in Guyana, Surinam, and Trinidad, and with Melanesian Fijians in Fiji. In these nations, Indians formed their own political parties, which have sometimes won elections and installed their leaders as prime ministers. But the ethnic rivalries have sometimes led to conflict, especially in Fiji. In Sri Lanka, some of the large Tamil minority have sought autonomy and more rights through violence, fomenting a civil war that has kept the nation in turmoil for several decades. Hostility against the Indian trading community contributed to their expulsion from Uganda in the 1970s; many of those expelled moved to Britain or North America. Indians have faced economic restrictions in Kenya and Tanzania.

Most Indians have adapted to the political and economic realities of their new countries, taking local citizenship and establishing permanent roots. Some have abandoned the traditions of their ancestors, but most remain conservative in culture. While caste identities and restrictions have often faded in the diaspora, most overseas Indians maintain their

Large overseas communities of Indians have sprung up in Africa, Europe, the United States, and other Asian countries; pictured here is the main street in one such neighborhood in Chicago, Illinois.

customs and religions, generally marrying within their own groups. Those who have emigrated more recently have forged a continuing connection to their families and ancestral villages in India, fostering the movement of peoples back and forth.

Japanese and Korean Emigration

Generally pushed by poverty, overpopulation, war, or repression, many people emigrated from northeastern Asia, forming cohesive communities in new lands. Many Japanese left their islands between 1850 and 1940. Some settled in Hawaii, many to work on plantations or in the canning industry. Today their descendants are the largest ethnic group in Hawaii. Other Japanese migrated to the Pacific Coast of the United States and Canada, some taking up farming in California. When the United States and Canada tightened their immigration restrictions on Japanese in 1907 and 1908, the emigrant flow turned to Latin America, especially Peru, Brazil, Paraguay, and Argentina. Many Japanese joined agricultural colonies or mining operations. Later the cultural networks they forged allowed many Japanese to leave wage labor for the ownership of businesses and farms. Leaving instability, Koreans also joined the flow overseas, especially to Hawaii between 1903 and 1905. During World War II many Japanese in the United States

and Canada were interned in concentration camps, often losing their property.

By the mid-twentieth century emigration from northeastern Asia flowed again to the Americas. Today some 1.5 million people of Japanese ancestry live in Latin America, and another million in the United States. Japanese-Americans have become one of the most affluent and well-educated ethnic groups. In a reverse migration, thousands of Brazilian-born Japanese have started moving back to the land of their ancestors. Korean migration to North America began in the 1960s on a large scale, many immigrant families opening grocery stores in large cities such as New York and Los Angeles. The new arrivals increased the total Korean-American population to some three hundred thousand.

Southeast Asian Emigration

Emigration from Southeast Asia has also been significant in the past 150 years, spurred by colonization, war, and political turbulence. Between 1875 and 1940 Indonesians, mostly Javanese, were recruited to work on plantations in nearby Malaya and North Borneo but also in Surinam and, on a smaller scale, the Pacific island of New Caledonia. Some fifty thousand Javanese today live in Surinam. During the early 1900s the French shifted a few thousand Vietnamese

to the South Pacific islands they controlled, mostly as plantation laborers. After the United States colonized the Philippines in 1902, Filipinos began migrating to Hawaii and the Pacific coast of the United States as laborers or farm workers. The migration has continued ever since. Today 2.5 million Filipinos live in the United States, many of them prosperous. Many Filipinos also work in the Persian Gulf, mostly in service industries.

The devastating wars in Vietnam, Laos, and Cambodia in the 1960s and 1970s generated another major migration, this time mainly of refugees. Between 1970 and 1985 over 2 million people fled those countries, mostly for the United States, Canada, Australia, or France, the former colonial power in that region. According to 2000 U.S. Census figures, the United States is home to approximately 1.3 million Vietnamese, 400,000 Laotians, and 200,000 Cambodians—as well as 150,000 Thai, 63,000 Indonesians, and 20,000 immigrants from Malaysia and Singapore. The Southeast Asians were part of a total Asian population of nearly 8 million in the United States, a thirty-fold increase since 1940.

The emigrant flow from East Asia, Southeast Asia, and South Asia to the Americas, Oceania, Europe, and the Middle East continues today, as people seek better economic opportunities, political stability, or personal security, continuing a human behavior—migration—that has a long history.

Migration, Indo-European

Indo-European languages were spoken from the shores of the Atlantic to eastern India and the westernmost province of China even before the first centuries BCE; today more than half the people of the world speak languages that belong to that same family. But scholars have debated the origins and earliest migration patterns of Indo-European languages, and the possibility of whether they derived from a common homeland.

The majority of the peoples of Europe and a substantial portion of the present and ancient peoples of western Asia speak closely related languages that all belong to the Indo-European language family. European colonial expansions and the spread of Euro-American culture have been so successful that nearly half the population of the planet now speaks an Indo-European language. Yet the place where this language family originated and the course of its earliest migrations have been topics of heated and inconclusive debate for more than two centuries.

The Early Indo-Europeans

The Indo-European language family can be divided into thirteen groups that may be briefly summarized, moving broadly from west to east.

Celtic Languages

During the period from about 500 BCE to about 1 BCE the Celts occupied much of western and central Europe and undertook raids into Italy and as far east as Greece and Anatolia (present-day peninsular Turkey). Today the Celtic languages survive only on the

periphery of Atlantic Europe as Gaelic (both Irish and Scots), Welsh, and Breton.

Italic Languages

In ancient Italy, Latin was by far the most successful of a group of closely related languages. Latin became the sole language of the Italian peninsula sometime around 100 CE and was then carried by Roman expansions over much of Europe. The Italic branch survives today in the form of modern Romance languages of French, Spanish, Portuguese, Italian, and Romanian, among others such as Catalan and Provençal.

Germanic Languages

Speakers of these northern and central European languages, such as the Goths, expanded from the north during the first millennium CE to occupy lands previously held by the Celts and other groups. The modern Germanic languages include English, Dutch, German, and the Scandinavian languages.

Baltic Languages

The Balts once occupied a vast territory from the Baltic Sea across northern Russia, but the expansion of Germanic speakers from the west and Slavic speakers from the south has left only the two modern Baltic languages of Lithuanian and Latvian.

Slavic Languages

During the first millennium CE the Slavs began their historical expansions in central and southeastern Europe. The major Slavic languages include Russian, Belorussian, Ukrainian, Polish, Czech, Slovakian, Slovenian, Serbo-Croatian, Macedonian, and Bulgarian.

Balkan Languages

The Indo-European languages of the ancient Balkan region are very poorly attested in inscriptions and in place and personal names recorded in neighboring classical languages. The major groups were the Dacians and Thracians, occupying roughly the areas of the modern states of Romania and Bulgaria respectively, and the Illyrians in the west Balkan region. The only Balkan language that survives is Albanian, which many suggest may have derived from the earlier Illyrian language.

Greek

The language of the ancient Greeks is attested from at least the thirteenth century BCE in the Linear B inscriptions of Late Bronze Age Greece and Crete. During the first millennium BCE the Greeks undertook extensive programs of colonization that carried them as far as Spain in the west and to the northern shores of the Black Sea in the east.

Anatolian

By about 1900 BCE documents from Anatolia indicate the existence of Indo-Europeans speaking languages of the Anatolian branch. The most notable and best studied of the early languages is Hittite. Some Anatolian languages survived to the beginning of the first millennium CE, but all are now long extinct.

Phrygian

With the collapse of Hittite power (c. 1380 BCE), the Phrygians established themselves in central Anatolia, and their language, attested almost entirely in inscriptions, survived into the first millennium CE.

Armenian

The Armenian language emerged in eastern Anatolia during the first millennium BCE after the collapse of earlier non-Indo-European states such as those of the Hurrians and the related Urartians. Although much of its vocabulary has been borrowed from its neighbors, Armenian still has a core vocabulary inherited directly from its Indo-European ancestors.

Iranian

The Iranian languages formed a vast chain of speakers from 700 BCE onwards that extended from the Scythians on the Black Sea to the Saka in western China. Most Central Asian languages (Bactrian, for example) are from the Iranian language family. The most abundant evidence of the presence of speakers of Iranian languages derives from ancient Persia (Persian), and Iranian languages predominate in modern Iran and Afghanistan.

Indo-Aryan

Closely related to Iranian is Indo-Aryan, the vast language group of the northern two-thirds of India from which many of the modern Indic languages, such as Hindi, Urdu, and Gujarati, derive. This group is abundantly attested in Sanskrit literature, which emerges by at least the end of the second millennium BCE. India also includes two non-Indo-European language families, Dravidian and Munda.

Tocharian

Extreme outliers, the two Tocharian languages were spoken in oasis towns along the Silk Roads in present-day Xinjiang, the westernmost province of China. They became extinct by about 1000 CE.

Europe also houses several non-Indo-European families. These include Basque, spoken in northern Spain and southern France, and the Uralic languages, which occupy a broad area of Europe's northeastern forest zone. Among the more notable modern Uralic languages are Finnish, Saami (Lapp), Estonian, and Hungarian.

The Proto-Indo-Europeans

Membership in a language family presupposes an ancestral language spoken somewhere at some time in the past that expanded to such an extent that its speakers came to speak regional variants that grew increasingly different from one another, though those variants were still related. The fragmentation of the late Latin of the Roman Empire into a series

of increasingly different Romance languages is a familiar example of how one language diverges into a number of different languages. A comparison of the grammars and vocabularies of the various Indo-European languages provides the evidence that they were once genetically related; that is, that they all derive from a common source. For example, the words *mother*, *father*, *brother*, and *sister* are rendered in Latin as *mater*, *pater*, *frater*, and *soror*; in Greek as *mētēr*, *pater*, *phrēter*, and *éor*; and in Sanskrit as *mātár*, *pítár*, *bhā́tar*, and *svásar*.

These correspondences reflect the fact that there was once a common language, which we term Proto-Indo-European, from which all of the daughter languages are derived. A comparison of the common vocabulary of the Indo-European languages permits linguists to reconstruct something on the order of 1,200–1,800 items of Proto-Indo-European vocabulary. (There were obviously many more words in the proto-language but we can only securely reconstruct a portion of these.)

The reconstructed Proto-Indo-European vocabulary provides all the semantic classes of words that we would find in any language, including parts of the body, verbal actions, pronouns, and numerals, for example. Of greatest cultural interest are those words pertaining to the natural world and to the economy, material culture, kinship, social structure, and religious beliefs of the Proto-Indo-Europeans. We know that the speakers of Proto-Indo-European had domestic animals (linguists have reconstructed Proto-Indo-European words for *cattle*, *sheep*, *goat*, *pig*, and *dog*; Proto-Indo-Europeans also knew the horse, but whether wild or domesticated is hotly disputed). They engaged in cereal agriculture (there are Proto-Indo-European words for *grain*, *barley*, *yoke*, *plow*, *harvest*, *winnow*, and *grinding stone*); stored and cooked their food in ceramic vessels; hunted and fought with the knife, spear, and bow; had some acquaintance with metals (there are words for *copper*, *gold*, and *silver*); and utilized wheeled transport (*wheel*, *wagon*, *pole*). In addition we can recover the names of at least some of the wild plants and animals known to the Proto-Indo-European speakers. In general, the arboreal evidence suggests a temperate climate (tree

words include Proto-Indo-European equivalents of *oak*, *birch*, *willow*, and *ash*) and forest and riverine animals (judging from words for *bear*, *wolf*, *fox*, *red deer*, *otter*, and *beaver*).

In general, linguists have estimated that Proto-Indo-European was spoken from about 4000 to about 2500 BCE, but this is largely an informed guess. Nevertheless, those dates do broadly conform with the dates indicated by analysis of their vocabulary for material culture, as such items as wheeled vehicles do not appear anywhere in the world before approximately 4000 BCE.

The Homeland Problem

For two centuries linguists and archaeologists have sought to determine the location or homeland of the Proto-Indo-Europeans and their subsequent migrations. In a vast literature that comprises both the brightest and the weirdest of would-be scholarship, the homeland has been located in space anywhere from the North Pole to the South Pole and from the Atlantic to the Pacific; in time the Proto-Indo-Europeans have been sought from the time of the Neanderthals (before 100,000 BCE) until the spread of use of the chariot (after 2000 BCE). The (Proto-)Indo-Europeans have been presented as everything from the bringers of a high culture who civilized Europe to the destroyers of European (proto)civilization; from peaceful farmers to warlike barbarian horsemen, depending on how scholars, sometimes acting under various national or ideological agendas, choose to interpret the limited data.

The difficulty of the whole enterprise, from a scholarly perspective, rests with the nature of searching for prehistoric linguistic entities: while the object being sought is strictly linguistic—a protolanguage—there is no purely linguistic technique that yields a convincing solution. That is not to say that there is not an arsenal of techniques that have been employed, but they just do not give convincing results when applied to the world's largest language family. One technique, for example, applies the notion of the “center of gravity” in the search for a language family's place of origin. The logic is that where we find the

Language shapes the way we think, and determines what we can think about. • **Benjamin Lee Whorf (1897–1941)**

greatest amount of differentiation (in other words, the greatest concentration of different languages, dialects, and so forth) is where the place of origin should lie, because it is in that area that the language family has existed longest and had the greatest amount of time to change. While languages invariably change over time, time is not the only factor of linguistic change. Topography, social structure, and contact with various foreign substrates, which are more diverse and inclusive than any single language, are also likely to influence language divergence.

Recognizing this, some linguists have sought to locate the homeland where they either find the greatest amount of conservation of the Proto-Indo-European vocabulary (presuming preservation to indicate the absence of foreign substrates and therefore the least movement from the homeland) or the least evidence for non-Indo-European loanwords. But neither of these techniques is satisfying. Because the various Indo-European languages have been attested at widely different times (with Sanskrit attested earlier than 1000 BCE and evidence for Lithuanian appearing two and a half thousand years later), it is hard to know how one can make a fair test of which has the most archaic vocabulary or the greatest number of loanwords. In fact, every Indo-European language possesses a sizeable vocabulary that cannot be demonstrated to derive from Proto-Indo-European. There is no evidence that any Indo-European language has sat in blissful purity over the past four or five thousand years. A measure of the inadequacy of these purely linguistic methods can be seen in the fact that the center-of-gravity principle has generally favored southeastern Europe (Greece and the Balkans) as the homeland, while the conservation principle has been adduced most often to support a homeland in either India or on the shores of the Baltic Sea (because of the conservative nature of Lithuanian).

Models

No matter where one places the homeland, there is an expectation that its location should at least be congruent with the evidence of the archaeological

record; that is, there should be some form of concrete evidence of the expansion of a language. A homeland at the North Pole obviously fails the test because there was no one there to speak any language. Other solutions have localized the Proto-Indo-Europeans in regions where there is simply no archaeological evidence that might suggest a movement consistent with the historical distribution of the Indo-Europeans, such as Scandinavia and the Baltic region, Britain and Ireland, the Iberian Peninsula, Italy, Iran, India, and Xinjiang. All of these areas are not only peripheral to the overall distribution of Indo-European groups, they also lack any evidence whatsoever for a major out-migration that might be equated with Indo-European expansions.

It is all the more ironic, then, that although the arrival of each Indo-European group in its historical seat (the Celts in Ireland, Latin speakers in Italy, Indo-Aryans in India) might appear to be a good starting place for backtracking to the Indo-European homeland, no dates for any of those arrivals have yet been determined. Instead, archaeologists are confronted with a series of windows of possible intrusions that may span up to four thousand years, as every new horizon of ceramic type, tools, or burial is (generally unconvincingly) associated with a potential invasion of Indo-European speakers. There is simply no region where there is an archaeological smoking gun—evidence for an invasion so massive that it must be associated with the arrival of the Indo-Europeans. The appearance of the Celts in Ireland has been set at anytime between 4000 and 250 BCE, while the evidence for the arrival of the Indo-Aryans in India is so ambiguous that many Indian scholars have argued that the Indo-Europeans have always been there (though these scholars do not explain how they could have spread elsewhere from India). A retrospective approach to Indo-European migrations (that is, one that starts from current locations and tries to wind the clock backwards) throws up too many dead ends; in the current state of play most prefer to start with a proposed homeland and trace putative out-migrations. There are two popular models for Indo-European origins that differ with respect to location, time, and means of expansion.

The Neolithic Model

Some associate the expansion of the Indo-Europeans with the spread of agriculture, a mechanism of language spread that has also been argued for the dispersal of other major language families, including Austronesian, Sino-Tibetan, Afroasiatic, and the Bantu languages. Farming entered Europe from Anatolia about 7000 BCE and passed through Greece and the Balkans both to the north and west across Europe, arriving at the Atlantic and Baltic by about 4000 BCE. This model supports the notion of demic diffusion, that is, the massive although gradual movement of people with a more productive economy into areas earlier occupied by people with a less productive economy (namely, hunter-gatherers), whom the newcomers absorb culturally and linguistically. Some argue that enormous language families can only be explained by such massive cultural change. The process is seen to have taken many generations and the emphasis, at least for southeastern and central Europe, has been on population replacement, generally by peaceful farmers. The attraction of this model is that it introduces a very powerful mechanism to explain how a language family could spread over such a vast area and extinguish all previous languages.

But the model also has its critics. Many do not believe population movement is responsible for the arrival of agriculture in northern and western Europe; they postulate a process of acculturation, the local hunter-gatherers adopting agriculture from their neighbors, and so the mechanism for language dispersal is not so compelling for the periphery of Europe. And when it comes to explaining the Indo-Europeans of Asia (who occupied an area at least equal to that of Europe), the earlier presence of agriculture there, which appears to be unassociated with the origins of agriculture in Anatolia, forces the proponents of the Neolithic hypothesis to abandon their demic model and adopt a segment of the second model: Bronze Age migrations (around 2000 BCE) of horse-using warriors from the steppe lands of Eurasia. The Neolithic model also seems to require migrations that are still several thousand years earlier than the

most recent technological items associated with the Proto-Indo-European vocabulary; in other words, it places Indo-Europeans in Greece and Italy several thousand years before archaeologists believe that they could have become acquainted with either the horse or wheeled vehicles, items that are reconstructed to Proto-Indo-European and whose names are inherited in the vocabularies of these regions. Finally, the suggested path of Neolithic expansions in Europe does not correlate very well with the linguistic relationships between the different Indo-European groups.

The Steppe Model

The second model suggests that the Indo-Europeans originated in the steppe and forest-steppe of eastern Europe (south Russia and the Ukraine). Proponents of this model argue that expansions began about 4500 BCE and continued in a series of waves both west into Europe and east into Asia. The farmers of the Neolithic model are here regarded as non-Indo-Europeans who occupied much of Europe *before* the expansion of the Indo-European languages. Rather than population replacement, the steppe model requires massive language shift among the indigenous population brought about by a minority of intrusive Indo-Europeans whose possession of the domesticated horse and ox-drawn wagon provided far greater mobility, and whose economy (pastoralism, with some agriculture) and social system were far more aggressive than those of the farmers of Europe. The mechanism for language shift lies here in either the political dominance of the intrusive Indo-European elites or the spread of Indo-European social institutions, which the local populations adopted along with the language associated with the new order. The key here—as with the spread of any language—is establishing what causes people to become initially bilingual and then to abandon their native language. Once the process was initiated, with minimal population movement the Indo-European languages could have spread from one region to another, arriving in the north and west of Europe by around 3000 BCE or more recently. The steppe model explains the Indo-

Europeans of Asia as further expansions of Bronze Age mobile warriors. The problem with the steppe model is that while evidence for migration can be found from the steppe lands into the lower Danube region, especially in characteristic burials under a mound (in Russian *kurgan*; the term gives the model its alternative name, Kurgan model), it is much more difficult to trace such movements beyond Hungary and the Balkans. Similarly, while there is clear evidence of expansions from Europe into the Asiatic steppe and partially into Central Asia, there is minimal evidence of any migrations further south into what would become the major civilizations of ancient Iran and India. Moreover, the presence in an area of many of the alleged traits of the steppe expansions, such as greater mobility, increased weaponry, and development of status burial, has been attributed to internal social processes rather than the impact of intruding Indo-Europeans.

The problem of Indo-European origins and migrations has been a major challenge to prehistorians, and the failure to develop a single fully convincing model is a salutary caution to anyone interested in tracing the path of migrations in the archaeological record. If increased doubt is the result of the type of intense discussion that tracing the roots of the Indo-Europeans has occasioned, then this does not bode well for many other hypothesized migrations that have seen far less scrutiny.

Military Engineering

Military engineering is concerned with the design, construction, and operation of offensive, defensive, and logistical structures in the course of warfare. These structures include forts and barricades, bridges, and trenches. An engineer's job might be to design and construct such objects, or to find a way to demolish them. Military engineers have been important participants in armed conflict from antiquity to the present.

Military engineering involves both construction and destruction. It is concerned with aiding troops to move about the battlefield, destroying enemy fieldworks, denying areas to the enemy, and providing defense works of substance. The military engineer has grown in importance through the ages, but has always been an important part of any army that was more than a mob of marauders.

Early Military Engineering

The Romans were among the first to make use of purposely deployed military engineers. One of the most impressive feats of military engineering in antiquity was Julius Caesar's bridge across the Rhine River. Roman engineers constructed a bridge spanning the Rhine at Koblenz, Germany, where the river is 366 meters wide and varies in depth from about 2 to 8 meters. It is reported that the bridge was completed in only ten days from the start. The achievement was remarkable.

Modern readers, however, should not be astonished that such feats were possible, and in such a short time. Military engineering was, even in antiquity, highly sophisticated. The ancient world had a great deal of

experience in building with wood and stone, as is witnessed by the survival of the pyramids and Roman buildings throughout Europe. Ancient sites in the Middle East and the Far East, and in Central and South America, prove quite conclusively that these ancient builders not only knew how to build, but they also knew how to make things last.

The Great Wall of China remains a monument to military engineering. Designed to protect the northern borders of China from marauding invaders, the earth and stone wall was built, rebuilt, and maintained by successive dynasties beginning more than two millennia ago. Similar elaborate structures, such as the Aztec causeway system or the Inca's network of roads, might not have been built exclusively for military purposes, but they did prove useful when those civilizations or empires came under attack. The use of timber for defensive walls is reported throughout antiquity, and military engineers soon learned to build them strong enough to deter all but the most professional armies; naturally, anything that can be built can be knocked down, and opposing military engineers soon developed methods of firing wooden walls to create access points for assaulting troops. Artillery of course was an additional source of destructive power, and was used to create holes in defenses.

The Assyrians were masters of the art of fortification, which was known in the Middle East even before 1000 BCE, but they were also good at knocking things down. They developed siege towers and battering rams. The siege towers dominated enemy walls, allowing troops to climb the defenses and get in; battering rams simply knocked holes in gates or walls, for the same purpose. The Japanese also built and relied on an extensive system of fortresses

of wood and stone; with many of the well-known castles of the sixteenth century evolving from wooden structures of earlier centuries. Ancient and medieval armies sometimes fought in the field, but they often confronted each other when one side was firmly ensconced within the defensive walls of a city or a castle. Caesar at Alesia (now known as Alise-Ste-Reine, near the source of the Seine River in France) used military engineering to great effect: he built an inner defensive wall around the defended town to keep the Alesians in, and then built another defensive wall around his troops, to keep any relieving force out. All construction was of wood, and the resulting walls were models of effectiveness that even today stand as examples of how to construct defensive walls.

Sieges created work opportunities for two groups of specialist troops. Artillerymen pounded the walls and defenses with their artillery (both early tension- and gravity-powered artillery and later guns) and engineers were employed within to construct and maintain the defenses, and outside to destroy them. Tunneling and mining became part of military engineering, and tunnels would be dug beneath towers with the tunnel supported by massive timbers to prevent cave-ins. Once complete the tunnel was then filled with timber and fired. The resulting failure of the previously installed supporting timbers would often bring the defensive work down, and examples of the results can be seen today in many European castles.

Even on the plains military engineering had an important part to play in open combat. It is thought that people took to riding horseback in Eurasia possibly as early as 4000 BCE. Just when horses were harnessed for war is unclear, but is thought that at least four to five thousand years ago horsepower was used to devastating effect against foot soldiers by coupling horses to two-wheeled chariots armed with a driver and a bowman or swordsman. Particularly important in terms of military engineering was the development of spoke-wheeled chariots around 2000 BCE.

Another particularly significant development in the evolution of military engineering was the gunpowder

Roman fortifications at Segontium, Wales, date from the second century CE. Photo by Chris Howell.

revolution (from around the thirteenth century on); both in respect to harnessing the explosive power of gunpowder and in terms of defending against it.

Trenches and Bridges

Another aspect of military engineering was the construction of trenches, or saps. To approach a well-defended town or castle assaulting troops needed cover, often already cleared away by the defenders. So trenches were dug, which got nearer and nearer to the target until the walls and defenses were within arrow or artillery range. Naturally the walls still needed breaching before troops could get in, but the engineers had that problem solved once they could get up to the foot of the walls.

River crossing has already been mentioned; it is important to move troops freely across the battlefield, and when maneuvering they must be able to get across rivers. Bridging works to supplement existing bridges, or to replace them if they have been destroyed, is an important task for the military engineer today as well as yesterday. Speed is of the essence, for a quickly built crossing can often gain time and provide the element of surprise always needed by attacking forces, and even by a retreating force. The importance of the Rhine bridges during World War II are a case in point: with the bridges intact the Allies could advance

quickly; without them they had the task of building new bridges under fire.

The Russians developed a bridging technique that confounded the Germans. Often Russian armor and vehicles were known to have crossed a river where there was no known bridge. Careful observation finally provided the answer: the Russians were building, under cover of darkness, bridges that were six inches under the water. This allowed them to move their tanks across the rivers to the complete surprise of the Germans. Engineers can come up with surprising solutions on occasions.

Vauban's Fortifications

Military defensive engineering was of particular importance once firearms and guns appeared on the battlefield. The French were masters of the defensive art, and Sébastien Le Prestre, Marshal Vauban (1633–1707), was the master of the art of siege-craft and fortification. Sieges had been part of military activity from the first moment that humans built walls and watchtowers, but Vauban made a science of what previously had been an art. In the attack the Vauban system prescribed an approach to the defenses by means of a series of trenches, first to bring the siege artillery within range, and then to get the infantry, archers, and engineers close to the base of the walls. The engineers then prepared fascines (bundles of wood) to fill in ditches and moats, and assault towers or mines to overcome the defenses of the outer walls. Often a further siege was necessary when the defenders had secondary defenses within the main walls.

Vauban also found time to create a system of defense: this was based on walls that were angled so that artillery shot and shells would have the least effect, as well as wide wall bases and countermining to defeat the enemy miners. As defense against attacking infantry Vauban's walls were pierced with firing loopholes (slots cut through the walls that were narrow on the outside, but wide enough on the inside to allow the firer room to move and use his weapon), and traps were built into which attacking infantry would be forced, after which they would be fired on

by cannon emplaced within the secondary walls of the defenses.

World War I

During World War I men disappeared into trenches after the first few months and then spent over three years fruitlessly trying to prove that the machine gun, artillery, and barbed wire could not stop a determined attack.

The infantry of the time were well trained in digging, as infantry have been since time began, but they were transformed into military engineers when the movement stopped. The Germans had outrun their supply lines, and both sides were exhausted by the early fighting and the punishing marches they were forced to undertake. The defenders, essentially the French and the British, had their backs to the wall when they decided to dig in to make a last stand before Paris. The Germans dug in as well, to try to get some rest before the final push. And that is how things stood for nearly four years.

Trench systems were of unbelievable complexity. There were three parallel lines of trenches (very similar to Vauban's system) with communication trenches running between them. In the front line, however, where shelling was most frequent, the trenches were often knee deep in water and mud, and in perpetual need of work to shore up cave-ins. British and French trenches were built in a less permanent way than those of the Germans, because the French and British were always planning to advance from their positions. The Germans were more methodical, and built much deeper, better underground living quarters, which were meant to be shell proof.

World War I was an example of siege-craft fought with more modern weapons. Rifle fire was far less effective than machine-gun and artillery fire, and the defender always had the advantage until tactics changed in the spring of 1918. Even the much vaunted tanks were incapable of making the necessary breakthrough because the engineers could not fill every shell hole in the battlefield, nor make every remaining bridge capable of supporting a tank.

Every gun that is made, every warship launched, every rocket fired, signifies in the final sense a theft from those who hunger and are not fed, those who are cold and are not clothed. • **Dwight D. Eisenhower (1890–1969)**

World War II

World War II saw military engineering develop its repertoire still further, and many of the techniques of that war still work today, albeit with even more sophisticated equipment. There were concrete bunkers to be built (the French Maginot Line and the German West Wall being two enormously expensive and extensive static defense systems), and the means to defeat them to be considered. There were portable bridges to be designed, which could be quickly erected across waterways where bridges had been destroyed (the British Bailey bridge is the prime example of this). Engineers also started to become specialist assault troops: the Germans included *pioniere* (or field engineers) in their frontline troops, and the record of their achievements includes many assaults on Vauban-style forts, which were reduced by means of demolition charges and flamethrowers. In World War I the Vauban forts withstood months of shelling, as shown by the battle of Verdun.

An early example of specialist engineer operations in World War II was the German glider-borne attack on the Belgian fort at Eben Emael, which obstructed the planned German advance across Belgium when the invasion of the West began on 10 May 1940. Landing on the roof of the fort, the German engineers disabled all the gun emplacements with shaped charges that had good concrete-defeating power.

Engineers were employed on every front in World War II, including in the Pacific War against the Japanese, where specialist engineering equipment, such as bulldozers, was often needed to supplement flamethrowers and demolition charges to defeat the defending bunker or “foxhole” positions. Throughout the war engineers both destroyed obstacles and built them, and they also built many airfields right behind the front lines.

More specialist engineering equipment was designed and used on D-Day, 6 June 1944, when Allied forces under General Dwight D. Eisenhower landed on the Normandy beaches to start the western push on Germany. Swimming tanks, anti-bunker tanks, and flamethrower tanks all arrived on the beachhead

at the same time as the infantry, and they were fundamental in enabling the British and Canadian forces to get through the first line of defenses and start inland. Surprisingly, the majority of this equipment was, although offered, not taken up by the American forces, who suffered their absence to some extent.

The Present Day

Military engineering is a special form of soldiering, and a fundamentally important one. Infantry cannot carry the engineering equipment needed to perform the tasks of the engineer, nor are they trained to do so. Modern engineer units are fully mobile, often carried in armored personnel carriers together with their specialist equipment. Field engineers today have enormous horsepower at their command, from tree-cutting power saws to fully tracked bulldozers and mine-clearing tanks. They can still both build things and blow them up, but far fewer people can now do the same job that took thousands to do only sixty years ago.

One task for which engineers receive little notice but that demands the admiration and respect of all is clearing booby-traps and mines. In conflicts in Africa, Bosnia, Afghanistan, Iraq, and many other areas of the world undetectable plastic, wood, or cardboard antipersonnel mines were strewn about the countryside with no regard for the future. These mines are now maiming and killing thousands of innocents, and it is the field engineers who are doing the slow and extremely dangerous job of clearing these areas. As in other arenas of military engineering, there is a good chance that it was military engineers who designed these mines.

Military Strategy and Tactics

Military strategy refers to the means by which states and other organized groups use force or the threat of force to obtain their objectives. Strategy tends to be broader in perspective than military tactics. Tactics involve the management and maneuver of military units in relation to each other, the enemy, and the terrain, all with the aim of achieving victory in battle.

Strategy and tactics are broadly defined terms that distinguish two levels or aspects of the techniques for applying power, in all of its forms, to resolve conflict. The application of power to secure a desired outcome in direct or imminent contact with an opposing force is the realm of tactics. Strategy is the application of power to obtain a desired outcome from beyond direct contact with an opposing force, and may well involve the decision to resort to direct contact with a foe at the tactical level. While the two concepts are opposite poles on a continuum rather than truly distinct approaches, they have proven useful in understanding many forms of conflict. But strategy and tactics emerged most directly from, and are understood primarily as, concepts for managing political and military struggle.

Ancient Origins

One of the earliest known students of strategy is still widely studied today. Scholars continue to debate when Sunzi (Sun-tzu) wrote *Military Strategy*, more widely known in the West as *The Art of War*, and the exact identity of that Chinese strategist. Whether written by the historical Sun Wu around 512 BCE or by an otherwise unknown author three centuries

later, the first great theoretical work on strategy benefited from centuries of Chinese experience and drew upon historical examples to support its conclusions. According to Sunzi, military force was but one component of a government's power. Once a ruler decided to resort to using that force he was wise to identify a desired outcome and leave pursuit of it to professional military leaders. These dual recognitions, that warfare is but one aspect of political power and that the application of military power calls for special expertise in addition to the actual skills of combat, have been shared by most complex human societies.

Sunzi contended that the decision to go to war was one of the most serious that a leader could face, and that the conduct of warfare required careful planning. The goal of warfare was forcing the enemy into submission, preferably without resorting to actual combat. Diplomacy, negation of the enemy's own efforts, limiting destruction and risk, and achieving maximum results at minimal cost were all aspects of strategy that both political and military leaders had to keep in mind. Deception, espionage, military preparedness, and combat effectiveness were among the components of strategy that could ultimately be used to maneuver an army into a position of such tactical advantage that any actual combat would be swift and one-sided. The mere threat of such an inevitable defeat could force an enemy into obedience, the height of strategic skill.

When strategy places opposing forces into proximity and both sides remain committed to conflict, tactics come into play. Despite their consistent focus on securing victory over an unwilling foe through the direct application of force, the specifics of tactics varied, and continue to vary, widely with the cultures,

technologies, and strategic situations involved. Tribal cultures might rely upon individual combat and improvisation, while more complex societies gradually developed a collective approach to formalized combat procedures. That contrast is vividly depicted in Greek literature, where the battles of Homer's *Iliad*, set in the Trojan War (c. 1000 BCE), are fought as a series of loosely coordinated individual combats quite different from the disciplined group methods and maneuvering armies of the Persian Wars (490–479 BCE) that Herodotus describes in *The Histories*. The armies of the Roman Empire, with their mixtures of infantry, cavalry, primitive artillery, and other specialized troops, carried this trend to an extreme in the ancient world. Flavius Vegetius Renatus (c. 375 CE) describes the complex tactics of the Roman legions through a series of military maxims in Book

3 of *De re militari*, a work that continues to interest students of the military arts.

Eurocentrism

Cursory examinations of the development of strategy and tactics after the end of the first millennium CE often focus on the West or employ Western concepts, leaving military scholars of all cultures potentially vulnerable to charges of Eurocentrism. The rest of the world certainly continued to advance the development of strategy and tactics after 1000 CE. Miyamoto Mushashi (1584–1645), for example, described the sword-fighting techniques of Japan's samurai in the *Book of Five Rings*. The lessons he provides through the tactics of sword fighting extend into both strategy and Zen philosophy, and are often discussed in the context of modern business techniques. But the developments in Europe during the second millennium CE that expanded its political, diplomatic, and military activities to the global scale also established the dominant conceptions of strategy and tactics.

One explanation for that fact lies in the origins of the Western nation-state, the social and political entity that came to dominate European, and eventually global, affairs by the end of the second millennium. The emergence and growth of nation-states following the Peace of Westphalia of 1648 largely depended upon their ability to muster military, diplomatic, and economic power under a central authority in the face of both internal and external opposition and or threats. As a result of that struggle European approaches to strategy and tactics became increasingly sophisticated. The same pressures, together with complex social changes, promoted the growth of military and civilian technology in a synergistic process that drove the continuous development of new approaches to managing conflict.

As Europe's dynastic struggles transformed into state contests its armies gradually abandoned their feudal structures to become professional organizations equipped with cannon and firearms. This development led to an age of relatively limited warfare

Utagawa Kokunimasa, *Our Army's Great Victory at P'yongyang Castle* (1894). Japanese officers look at maps and review the progress of battle taking place outside the fortress at P'yongyang. Library of Congress.

in the seventeenth and eighteenth centuries as enormously expensive professional armies adopted rigid tactical systems and a strategy based upon position and maneuver rather than direct engagement. The resulting wars in Europe unwittingly resembled the strategies promoted by Sunzi in China two thousand years earlier, as military and political leaders struggled to win armed contests with minimal loss of life and treasure. The works of the great French military engineer Sébastien Le Prestre, Marshal Vauban (1633–1707) exemplify the era.

Vauban designed an elaborate system of elegantly engineered fortifications to defend France, providing the setting for ponderous wars of maneuver in which tactics became mechanical exercises. Highly disciplined soldiers moved in prescribed patterns even under hostile fire. Military campaigns focused upon the conquest of key locations rather than the subjugation or destruction of the enemy and so became works of logistics and engineering little different from their fortified targets. Recently developed sailing warships equipped with heavy cannon began engaging in elaborately scripted maneuvers, codified in England by the Fighting Instructions of 1691, which limited both the risks and effectiveness of naval engagements as they restricted tactical options.

Many of the limitations of Europe's tactics and strategies were imposed by the technology of the period, but those limitations did not prevent European nations from successfully applying the power and discipline of their armed forces against less technologically advanced opponents as the West expanded its influence in other regions. The very effectiveness of European arms and techniques, including the political organization of the state, promoted their eventual adoption or assimilation by colonial subjects and opponents alike in forms adapted to local requirements.

At the same time, European expansion inevitably led to resistance, and in most cases that resistance came from small outnumbered and outgunned fighters who could not hope to confront the state on its own terms, hence they took to guerrilla tactics. Guerrilla warfare is an irregular or asymmetrical form of warfare whereby combatants rely on highly mobile hit and run military tactics in the form of ambushes and raids on larger and better equipped but mobile formal armies. In turn, guerrilla warfare is countered with counter-insurgency techniques and warfare. This is a form of warfare and counter warfare that has been employed anywhere that there is an asymmetry between the opposing combatants.

In response to such tactics, Europeans, and others, have also learned from the successes and failures that resulted from applying their codified manuals of arms and tactical systems against the warriors of other cultures, increasing the breadth of their formal study of strategy and tactics.

The advent of truly national wars in the wake of the French Revolution expanded the scope of European strategy and restored fluidity to tactical systems on both land and sea, largely due to the influence of France's Napoleon Bonaparte (1769–1821) and Britain's Horatio Nelson (1758–1805). Industrialization expanded the lethality of the armies and navies employing the new techniques it promoted, and armed forces around the globe struggled to adapt to the rapid changes in warfare. When the American Alfred Thayer Mahan (1840–1914) began constructing a theory of maritime power based upon the British experience Japan became one of the first nations to construct a navy accordingly, indicative of the growing dominance of Western approaches to strategy and tactics. But the twentieth century caught all nations unprepared.

Twentieth Century

Indicators of the horrific potential of industrialized total warfare in the nineteenth and early twentieth centuries went largely unheeded, and the devastation of World War I (1914–1918) shocked the world when increases in weapons effectiveness and logistical capabilities left the nations of western Europe without effective offensive tactics. Efforts to break the resulting stalemate on the Western Front accelerated the development of weapons such as the airplane, tank, submarine, and poison gas. The war's aftermath produced a series of arms control agreements and the League of Nations, as world leaders sought to expand diplomatic options and place limits upon military capabilities. But the same period expanded the new concepts of strategic bombing and unrestricted submarine warfare, designed to destroy an enemy's will and ability to resist by targeting its

civilian population, and the mobile, combined-arms warfare that would be implemented by the Germans. Wars had become so complex that a level between the strategic and tactical, the operational, gradually began to enter the military lexicon. The operational level of conflict pursues goals and approaches defined by strategy by orchestrating the elements of power to obtain tactical success, linking the extremes of the strategic–tactical continuum.

World War II (1939–1945) demonstrated this continuum as nations pursued both individual and collective strategies, materialized in operations throughout the world that produced innumerable engagements at the tactical level. As a total war for all involved, every aspect of national power became a tool of strategy that could be harnessed. That concept of national power continued to define many countries' approach to the Cold War (1945–1991) that followed.

The introduction of nuclear weapons, combined with the growing range and accuracy of missiles, particularly intercontinental missiles, brought a new potential to warfare, and the strategies that nuclear powers developed grew out of the doctrines of strategic bombing. Deterrence through mutually assured destruction became a stated goal of some national policies. Some nations developed nuclear weapons for tactical use, but the immense destructive power of fission, and later fusion, bombs and the difficulty in distinguishing between their tactical and strategic roles has prevented their tactical employment thus far, save for in Japan at the close of World War II. The threat of escalating from conventional non-nuclear to tactical, and then strategic, nuclear warfare played a large part in restricting the Cold War between the coalitions led by the Soviet Union and the United States to indirect military action and other forms of conflict.

Twenty-First Century Outlook

The twenty-first century is presenting notable challenges to the predominant strategic and tactical

Float like a butterfly, sting like a bee. • Muhammad Ali (b. 1942)

systems that emerged out of the Western tradition, with their emphasis on state actors, professional militaries, and distinctions between legitimate and illegitimate targets. The end of the Cold War is producing a multipolar world dominated by the split between the beneficiaries and opponents of economic globalization, and tactics and strategies, such as guerrilla warfare, long relegated to the periphery of military and diplomatic conflict are becoming more prominent. It should not be surprising that many of the techniques weak groups are choosing to use in conflicts against the powerful are regarded by their targets as criminal or uncivilized behavior. They are the strategies and tactics that criminals, rebels, and other weak groups have traditionally used to force behavior upon or secure an outcome from a stronger foe.

The resulting struggles between the strong and the weak are defined as asymmetrical warfare. While the use of terror and intimidation, indiscriminate destruction, kidnapping, and suicide attacks are all ancient tactical and strategic options, they pose a serious challenge to security forces and diplomatic systems developed to pursue different strategies. The world's leading powers will adapt their strategies and tactics to the increased prominence of this formerly marginal threat as they

continue to face more conventional means of resolving conflicts.

Military Training and Discipline

Masses of men, however well armed, will never be a match for a well-trained and highly disciplined military force. Since the birth of nation-states, an army has been part of the organization of the state, but armies have not always been a permanent feature within states.

In early history trained armies were often brought into being at times of crisis and were disbanded once the moment had passed. At the same time certain states and tribes with superior training and experience in military arts and strong discipline began to hire themselves out as mercenaries. In both scenarios, training and discipline go hand in hand to transform an armed group in a viable army.

Training and Punishment

From ancient times, all military leaders have attempted to instill discipline into their troops, and the best method of doing this is training, backed by military discipline. Initial training puts men into groups in which they will perform foot drill and basic tasks; this teaches the men to work together and to work for the good of the group. As the training progresses the group is expanded and often the discipline becomes harsher. Instructors of trainee soldiers always have to balance rewards and punishments to ensure that morale is maintained, even though punishments may have some short-term negative effects on the men's sense of well-being. The aim of training and the discipline that goes with it is to produce a soldier who is capable of operating and fighting effectively in concert with the other members of the armed forces. He should be able at the same time to exercise self-

discipline, once more for the betterment of all, by being well organized himself.

Discipline in the military has always been a matter of concern for nonmilitary people; it is best expressed as another method of training. Soldiers who have no self-discipline make mistakes and may be prone to carelessness, which can lead to mistakes and death. By contrast, cohesive discipline within a group of soldiers brings with it higher morale and thence higher fighting effectiveness. In training and later, because mistakes can cost lives, punishments are graded according to the seriousness of a transgression, just as in civilian life. The German army for a long time used the phrase *Schweiss spart Blut* (sweat saves blood), which encapsulates the whole ethos of military training and discipline. The ultimate punishment for soldiers is the death penalty, until recently meted out for acts such as cowardice in the face of the enemy.

Early Armies

The Assyrians were among the first peoples to create an army, which was a natural expression of their way of life; they were bold men full of energy who were adept at big-game hunting, from which military activity was a natural progression. The Assyrian army at the time (c. 700 BCE) was built within the state, and the main business of the state was war. The Assyrian army was trained in infantry and cavalry maneuvers, field engineering, and sieges, and was supported by a logistical system capable of supporting 100,000 men in the field. Their tactics included the use of terror, and whole populations were either killed on the spot or transported to slavery. The discipline within this army was draconian.

In the seventh century BCE the Greek city-states refined the tactical formation known as the phalanx, which had first been developed by the Sumerians. The phalanx was a block of men—in the case of the Greeks, eight men deep—that marched forward in solid ranks, which was a frightening sight for the enemy.

The ancient Greek city-state Sparta, known in history for its military prowess, was founded around 1000 BCE and initially was little different militarily from the rest of Greece. However, under Lycurgus (ninth century BCE) Sparta became the preeminent military state in Greece, and the training and discipline of its troops became legendary.

The Hellenistic World and Rome

As civilization progressed, armies became standard parts of all states, with the parallel mercenary system alongside. Mercenaries were of particular value because they were paid professional soldiers; soldiers who were not mercenaries were often farmers and peasants, called up for service when needed by their superiors within their own state. Mercenaries were well trained and always available. As long as they were paid, they fought well and were often decisive in battles and campaigns because of their professionalism.

As warfare developed training had to become more complex; troops trained in a limited number of drill maneuvers would soon be outmaneuvered. Philip II of Macedon (382–336 BCE) established a national army that was transformed into a magnificent fighting machine by means of training and discipline allied with careful organization. The heavy infantry were so well trained that they were more maneuverable than the Greek phalanx, a real mark of professionalism. Heavy infantry, by virtue of their origin in the more moneyed middle classes, were better educated and equipped (having bought their arms and equipment themselves), and their training used their loyalty and intelligence to produce cohesive, effective and maneuverable fighting units.

In the Roman army training and discipline combined to produce a force that was rarely defeated

simply because it was so well trained that it could react to adversity and be effective in very difficult situations, times at which opponents would often cut and run. The Roman army was officered by men who had fought initially in the ranks, and who had proved themselves in battle as both courageous and capable

Marble statue of a helmeted hoplite, fifth century BCE, from the Archaeological Museum at Sparta, Greece. Hoplites, or citizen-soldiers who served many ancient Greek city-states, received basic military training in the phalanx formation and were responsible for procuring and maintaining their own armor and spears.

of command. Their men were drilled by their seniors who had battle experience, training which emphasized the importance of maintaining formation, fighting cohesively and always being loyal to their unit and their country. The great incentive for rank and file Roman soldiers was that when discharged after service they would receive citizenship and land.

Early Chinese Military Training and Discipline

The Han dynasty (206 BCE–220 CE) built up a field army of infantry, cavalry, chariots and crossbowmen. The effective use of such an army required detailed training, but there is little in extant literature to guide the student of the period. It seems that the army promoted at least partly on a merit system (as well as seniority), and that the mass of men were assembled by means of conscription into a semi-regular militia, liable to serve at any time they were needed. Men between the ages of seventeen and sixty had to serve for a long period. One treatise of great importance has survived and is still studied today: *The Art of War* by Sunzi (Sun-tsu). It is probably the earliest work on the subject and was read by many of the leading soldiers of the period, as well as by later practitioners.

The Mongols and Cavalry

In agrarian states, cavalry were recruited initially from men who could afford to keep a horse. For foot soldiers cavalry presented a greater threat than opposing foot soldiers because cavalry can move more quickly (and turn a flank), and men are naturally alarmed by the sight of horse riders approaching en masse. Among pastoral peoples such as the Xiongnu (flourished third–eighth centuries CE) or the Mongols, cavalry fighting arose naturally, as pastoralists rode horses in the care of their flocks.

The Mongols, who dominated eastern Eurasia in the thirteenth century, are often depicted as a horde, winning their battles by weight of numbers, speed, and surprise. In fact, the Mongols' numbers were often less than those of their opponents, but their

technique of sending units of men in from many directions gave the impression of many more numbers than they actually had. The Mongols were exceptional horsemen and skilled at arms. Accustomed to life on the move, they were untroubled by weather and hardship and were rarely sick.

Every unit was trained in precise maneuver and was capable of extremely rapid reaction. Practice before battle meant that every component of the Mongol army could cooperate effectively with all other parts of the army, and this was the result of interminable training sessions where mistakes were recognized and ironed out to produce a smooth tactical effort. The method of training was above all based on repetition, so that initial mistakes were trained out, and men reacted cohesively in battle, a primary requirement of all good armies.

The Middle Ages: Evolving Weapons Systems

Weapons in use in Europe during the Middle Ages had changed little from those used in ancient times: infantry were equipped with spears, axes, clubs, or swords, cavalry with sabers. One new weapon, however, was the longbow, which was decisive in the battles of Crécy (1346), Poitiers (1356), and Agincourt (1415), three English victories over the French in the Hundred Years' War, with Agincourt deciding the war in favor of the English. Armored knights on horseback and heavy infantry armed with shorter-range crossbows were mown down by the concentrated fire of the English (or rather Welsh) archers. At Agincourt, although weight of numbers brought the French knights to the English front line, English archers picked up swords, axes, and daggers and attacked the almost exhausted French nobles through gaps in their depleted line of battle, causing terrible casualties.

Firearms also began to be seen, with Europeans beginning to use cannons in the fourteenth century. There were two types: cannons made of copper or bronze alloys, which fired lead shot, and wrought iron cannons, which fired iron balls, stones, or shrapnel.

Never interrupt your enemy when he is making a mistake. • **Napoleon Bonaparte (1769–1821)**

Cannons were employed in sieges, common in the battles of the Middle Ages. The matchlock, a device for igniting gunpowder, was developed in the fifteenth century and made possible the later development (in the sixteenth century) of the musket. Because muskets took a long time to reload, musketeers were protected by pikemen for a long time after they appeared on the battlefield. Training involved loading the musket in a rigid number of steps that had to be performed in sequence, otherwise the weapon would not fire or would be incorrectly loaded and injure or kill the user. Musket training was by its nature devoted to getting men who were being attacked to remain steady and to load and reload their muskets, delivering perhaps

two or three shots at the enemy per minute. Musketeers also had to be trained to advance to within fifty paces (the range at which muskets were usually fired) in good order; they were to maintain their position in the line no matter what happened.

Throughout this period of warfare the infantry fought as a large mass. In the early days this was to present a block of swords or pikes to the enemy and deny him the chance to get to the rear, where great slaughter could be perpetrated; later it was to ensure a maximum concentration of arrows onto the target, or to bring the mass of the cavalry to a specific point.

The Turkish Janissaries were first raised at the end of the fourteenth century, and consisted of former

During the Cultural Revolution (1966–1976) in China, military units drilled in the fields.

Christians captured in childhood and raised as fanatical Muslims. They were to be a force of great renown for some five hundred years thereafter. Their discipline came from the strictures of the Muslim religion, and their ferocity and courage were much respected. The Corps of Janissaries was never large, but they were skilled infantry who would build fortifications as bases around which the less effective Turkish cavalry could maneuver.

Military Training in Japan, 1192–1868

For the better part of a millennium, the islands of Japan were ruled by various military governments, and the warrior elite were training in martial arts and military skills from childhood. House codes prescribed appropriate behavior and supported warrior ideals.

Although there were notable cases of betrayals during the long centuries of military rule, the ethic of absolute loyalty was quite real, as exemplified by the practice of following one's lord in death by committing suicide. During the Edo period (1600/03–1868), there were specialized schools of military training that the military class (which for most of the period, ironically, did not engage in warfare, as there were no wars) attended.

Training Individuals for Modern Warfare

Rifled firearms, which increase the range and accuracy of a fired bullet, were first developed in the fifteenth century, but they were difficult to manufacture and remained the weapon of sharpshooters until the eighteenth century. The nineteenth century saw a further innovation: the machine gun, which was capable of firing off hundreds of rounds per minute. In response to this new weapon, it became necessary to train men to disperse on the battlefield so that they did not present a massed target. In less than fifty years (from the U.S. Civil War to the Boer War) the soldier appeared as an individual. This individual still had to work as part of his team, his unit, and

his formation, but his movements on the battlefield were intended to enable him to fight and stay alive. Training to improve individual skills on the battlefield therefore became more important.

In the days of the line, when men fired on command, training focused on getting the men to stay in line and to fire in concert. Modern warfare, however, requires men often to fire at will and to move on an individual path toward the enemy. This type of training acknowledges that today's soldier is a far cry from the "cannon fodder" of two centuries ago, and that soldiers are important assets to be trained in avoiding personal injury while closing in on the enemy. However when defeat was facing both the Germans and the Japanese they put fewer well-trained personnel into the field, and all involved recognised that this was a desperate attempt at postponing defeat by means of suicidal operations. The Japanese went one step further with the "kamikaze" system, which involved flying aircraft into enemy warships with the certain prospect of death.

Modern training methods still begin with the need to act concertedly and in step with others. However, battlefield training takes the form of individual education in fieldcraft, map reading, communications, camouflage, survival, weapons training, and many other aspects of modern soldiering.

Millennialism

Millennialism is the belief in an imminent transition to a collective salvation, either earthly or heavenly, accomplished according to a superhuman or supernatural plan. The term (based on *millennium*, meaning “one thousand years”) is drawn from the New Testament book of Revelation (Apocalypse), which predicts a thousand-year reign of Christ on Earth.

Religious and political movements inspired by millennialism, the belief that collective salvation (either earthly or heavenly) is imminent—and based on and carried out by a superhuman or supernatural plan—have had a major impact on world history; these include the theological revolutions associated with Christianity, Islam, and Chinese combinations of Daoism and Buddhism, and secular movements such as Communism and Nazism. The human hope for a perfect world has been perennial, at least since the founding of the Zoroastrian religion, which possibly dates from as early as about 1000 BCE. Millennial groups oriented toward a heavenly salvation have occasionally startled the world by opting to leave earthly life via group suicide, as was seen in the 1990s with the Solar Temple in Switzerland, Quebec, and France, and Heaven’s Gate in the United States. If earthly salvation for an elect group of people in a millennial kingdom is demonstrated to be impossible, then believers can shift easily to expecting a heavenly salvation, which may have been the case as early Christianity was institutionalized and became more accommodated to mainstream culture in the Roman Empire.

The millennial belief in an imminent transition to a new realm of existence has had a great impact

on world history in many times and places, and has been associated with a range of behaviors. Millennial beliefs can motivate people to convert to entirely new religions, as with early Christianity and Islam, or strengthen their existing faith as they await divine intervention to destroy the old order and create the new. Millennialism can motivate people to engage in social action to improve the world and in spiritual disciplines to transform themselves, but it can also motivate them to commit revolutionary violence in attempts to eradicate an evil society and create the millennial kingdom. Millennialism does not necessarily have to result in violence, and when millennialists are caught up in violent episodes, they are not necessarily the ones who initiate the violence. Numerous millennial prophets and messiahs and their followers have been assaulted or executed because of the threat they pose to the established order.

Millennial Leaders

Millennial movements are often stimulated by someone claiming to have received a new revelation. In the study of religions, the term *charisma* refers to the belief that an individual has access to an unseen, superhuman source of authority. It is impossible objectively to validate the person’s claim: people either accept it on faith or reject it. If others do not believe the individual’s claim to revelation or empowerment, then the person does not have this kind of socially constructed charisma.

Both prophets and messiahs have charisma in this sense. A prophet is someone who is believed to receive revelations, perhaps about the imminent transition to the millennial kingdom. Although also

The Millennium Wheel in London, England, was built to commemorate the beginning of the third millennium CE.

a prophet, a messiah is, in addition, believed to have the superhuman power to create the millennial kingdom. There can be religious apocalyptic prophets, such as Muhammad, and religious messiahs, such as Jesus Christ, who according to the gospels was also an apocalyptic prophet. There can also be secular messiahs, such as Adolf Hitler, who claimed to be empowered by “nature” to create the Third Reich as the millennial kingdom for the German *völk* (folk).

Millennial movements do not necessarily have to have prophets and messiahs. They may arise from the widespread anticipation and/or fears of a number of people, such as the diffuse Euro-American (white supremacist) movement in the United States at the end of the twentieth century and the beginning of the twenty-first, which includes Identity Christians, racist Neopagans, neo-Nazis, and secular survivalists and warriors expecting an apocalyptic conflict with the federal government.

Main Patterns of Millennialism

Scholars now use the term *millennialism* (or *millenarianism*) to refer to two common patterns, which are not mutually exclusive; millennialists may shift from one pattern to another in reaction to different circumstances. Both types of movements may or may not have prophets and/or messiahs.

Catastrophic Millennialism

Catastrophic millennialism, often termed apocalypticism, anticipates a catastrophic transition to the millennial kingdom, either earthly or heavenly. Human nature and society are so evil that society has to be destroyed and created anew. Christians who have these expectations are often categorized by scholars as “pre-millennialists,” because they expect Jesus Christ to return *first*, defeat evil powers, destroy the

This Mexican broadside from 1899 shows skeletons in pandemonium as they anticipate the end of the world.

I worry that, especially as the Millennium edges nearer, pseudo-science and superstition will seem year by year more tempting, the siren song of unreason more sonorous and attractive. • Carl Sagan (1934–1996)

current world, resurrect the dead, judge all people, and then create the millennial kingdom (either earthly or heavenly).

Most catastrophic millennialists wait for divine intervention to carry out the catastrophic events. Some, such as the Branch Davidians and some Identity Christian communities, may arm themselves for self-protection during the tribulation period believed to lead to the end-time events; if they are attacked they will fight back. Some, such as a succession of violent movements in Christian medieval Europe, become actively revolutionary. If the revolutionaries do not have a critical mass they become terrorists.

Progressive Millennialism

Progressive millennialists believe very strongly in progress, and are typically concerned with creating a millennial kingdom on Earth. They believe that humans acting according to a divine or superhuman plan can progressively create the millennial kingdom. Christian progressive millennialists are often termed “post-millennialists” by scholars to indicate that they believe they must do God’s will by creating the conditions for God’s kingdom on Earth, and *then* Christ will return.

Progressive millennialists include Protestants working peacefully to improve society by carrying out the Social Gospel, as well as post-Vatican II Catholics with a “special option for the poor” working for social justice. Logically, however, progressive millennialists could arm themselves if they felt their community was threatened and fight back if attacked, but this possibility has not received much study. And some progressive millennialists, wishing to speed progress up “to an apocalyptic rate” (Ellwood 2000, 253), become revolutionaries. They are willing to kill others and to carry out massive violence to accomplish their vision of the millennial kingdom. Scholars have identified Nazism, the Marxist Khmer Rouge regime, and Mao Zedong’s Communist Revolution and Great Leap Forward as examples of revolutionary progressive millennialism.

On the revolutionary end of the spectrum, there appears to be little difference between catastrophic

and progressive millennialists, other than the latter having a strong belief in progress. Both types possess a rigid dualistic outlook, seeing situations and people in terms of good versus evil, us versus them, and they kill to accomplish their millennial dreams.

Nativist Millennial Movements

Nativist millennial movements, sometimes called “revitalization movements,” result when a people feels colonized and oppressed by a dominant power and its accompanying bureaucracy. Their traditional way of life is being destroyed and they often are losing their land and means of livelihood. They wish for a return to an idealized earlier time for their people, which they imagine to have been perfect. They are millennialists in that they expect an imminent transition to a collective salvation, which will eliminate their oppressors. These movements have been found in every part of the world in response to colonialism.

In the United States nativist millennialism can be seen in the nineteenth-century Ghost Dance movement, a response by Native Americans to removal from their lands and destruction of their traditional way of life. Beginning in the late twentieth century, nativist millennialism could be discerned also among certain white people in the United States, who imagined themselves to be the “natives” of America. Living in the countryside and towns, and also in cities, they felt oppressed by federal agencies, and believed that their traditional way of life was being destroyed by increasing ethnic diversity, changing gender roles, and greater acceptance of diversity in sexual lifestyles. This unnamed but influential movement could be called the Euro-American nativist movement.

Some nativist millennialists, like the Native American Ghost Dancers, may expect divine intervention to remove the hated oppressors in response to a magic or sacrificial ritual such as the Ghost Dance, which was intended to bring the return of the ancestors. Some, like the Pai Marire movements among the Maori in nineteenth-century New Zealand, may alternate between expecting divine intervention, committing active revolutionary violence, and progressively building their own separate communities. Nativists’ actions

depend on a variety of factors, including whether they are left alone to build their perfect societies or they are attacked.

Millennialism in the Twenty-First Century

Millennialism will remain an important factor in world history. It might be stimulated by significant dates, such as 2000, but the hope for the collective salvation has existed for thousands of years and will not disappear. In the new temporal millennium, Christian Dispensationalists, for instance, interpret events in the Middle East as fulfilling prophecies leading to Christ's Second Coming; they expect that the faithful will be "raptured" into heaven and thus escape the catastrophic end-time events. With the terrorists attacks of September 11, 2001, al-Qaeda became the most visible segment of a diffuse and widespread revolutionary Islamist movement that aims to destroy what is seen as a confederation of "unbeliever" nations, including the United States and "hypocrite" Muslim nations aligned with the West, to create the perfect Islamic state enforcing sharia (Islamic law)—a Muslim vision of the collective earthly salvation. Those revolutionary Islamists who die for the cause are assured that they will receive immediate rewards in heaven—a very dangerous combination of expectations concerning earthly and heavenly salvations.

While people in all parts of the world continue to interpret catastrophic tragedies and oppression through an apocalyptic lens, many progressive millennialists, from Jews, Christians, and Muslims to Hindus, Buddhists, and New Agers, still hope and work for a peaceful world.

Miranda, Francisco de

(1750–1816)

SOUTH AMERICAN REVOLUTIONARY

The South American revolutionary Francisco de Miranda was not an exceptional military talent, a gifted diplomat, or an innovative thinker. He was a master propagandist and tireless promoter of the one idea that animated his entire life: the emancipation of Spanish America. For his constant efforts on four continents, his countrymen have given him the title of Precursor.

Born in Caracas, Venezuela, to an entrepreneurial émigré merchant from the Canary Islands, Francisco de Miranda grew up in a large family and attended college in Caracas. Miranda's father purchased a captaincy in the Spanish army for him, and the ambitious young man set off for Madrid in 1771. Thus began the adventures of a man who would one day become a revolutionary obsessed with the emancipation of South America.

Miranda did not return to Venezuela for nearly forty years. Once in Spain, Miranda set about enjoying all that life in Europe offered. Beginning a pattern that lasted throughout his lifetime, he exploited his considerable charisma to secure the patronage of wealthy men and women who paid his expenses and invited him to their salons. Miranda entered into active duty and saw service in the Spanish garrisons in northern Africa. He proved to be an unusually difficult soldier, however, openly admiring his Moorish opponents and sympathizing with their desire to rid their soil of a foreign military presence. Starting to dream of liberating his own countrymen, Miranda was reprimanded, even jailed, several times for his insolence and outright disobedience. He requested a transfer to the Spanish fort at Cuba several times

before permission was finally granted and he set sail for the Caribbean in 1780.

Once there he again enjoyed the protection of important people; Cuban governor Juan Manuel Cagigal liked the brash young man and invited him to participate in the expedition that retook Pensacola from the British. He later coordinated the efforts of certain Cubans to supply the North American patriots, sending critical financial aid to Admiral de Grasse in Chesapeake Bay. In 1783, he was entrusted with an important mission to Jamaica to negotiate a prisoner exchange but, while there, may have had some secret business of his own. When he returned to Cuba, rumors started to circulate that Miranda had been enlisted as an English spy. Although the charges were never proven, he had already become so transfixed by the idea of liberation and alienated from the Spanish Empire that he decided to defect. Under cover of darkness, Miranda stole away to the United States to witness the birth of a new American republic.

Francisco de Miranda spent nearly two years, 1783 and 1784, traveling throughout the United States, stopping in Charleston, Philadelphia, New York, Boston, and many smaller towns in between. During his extended tour, he visited many important battle sites and talked with many important military and political leaders of the new nation. Miranda became particularly close with Alexander Hamilton, Henry Knox, and the extended family of John Adams, whose son-in-law William Smith became a frequent travel companion. He met George Washington and the Marquis de Lafayette, both of whom left him unimpressed. Throughout his tour,

Lewis B. Adams, *Portrait of Francisco de Miranda* (c. 1844). One idea animated Francisco's entire life: the emancipation of Spanish America.

Miranda sought out experiences that would help him understand the vast political experiment taking place around him.

In 1784, Miranda sailed to England to continue his useful politically motivated tourism. He ventured northward to Scotland in a failed effort to meet Adam Smith, but nonetheless managed to meet important academics and inventors in Edinburgh and at Oxford University. The Spanish embassy kept close watch on this deserter, sending back frequent reports on his activities and meetings. In 1785, Miranda and William Smith decided to take a tour of Europe. They sailed for the Netherlands, and from there continued onward to Prussia, where they arrived in time to witness maneuvers being held by Frederick the Great's much-vaunted military. Parting ways with Smith, Miranda continued southward to Italy, where he held secret meetings with exiled Spanish-American Jesuits. Miranda's educational tour continued to Greece and Turkey, where he reverentially visited all the sites of classical antiquity and studied current military practices and weaponry.

Miranda headed northward to the Crimea just in time to meet Prince Potemkin and Catherine the Great on their tour of the Ukraine in 1786. Enjoying royal favor, he spent a year in Russia with Catherine, who later granted him the aristocratic title of count and promised him perpetual protection in her embassies. Miranda traveled through Scandinavia and back to central Europe, ending his tour in France. With his impeccable timing he arrived in Paris in the momentous month of May 1789, when the first steps toward revolution occurred.

Feeling sympathy with the cause of liberation throughout the Atlantic world, Miranda joined the forces of the French Revolution in 1793. He commanded their northern troops in Belgium but failed to secure his territorial gains when material support from France was slow to arrive. Miranda was a competent military leader, but quickly fell victim to the Jacobins' political intrigues. Maximilien Robespierre, in particular, despised Miranda for his adherence to positions advocated by the Gironde (a group of moderate republican deputies). In 1794, Miranda was arrested, put on trial for treason, and jailed for nearly two years; when he was released he returned to England to try to interest Prime Minister William Pitt in a scheme to liberate South America. He remained devoted to the ideals of the early French Revolution, though, and eventually founded a Jacobin club in Venezuela.

Tired of waiting for William Pitt and the English Parliament to approve his expeditionary force, Miranda decided to ask his old friends in the United States for assistance. He sailed to America in 1805 and quickly secured an audience with President Thomas Jefferson and Vice President James Madison, who expressed their interest, even their tacit approval, but refused to grant him any official support. Nevertheless, Miranda's friends in New York were more enthusiastic and managed to outfit a ship, which he named the *Leander*, after his young son. Dozens of idealistic young men volunteered to join his expedition, which landed at Coro, in northwestern Venezuela, in 1806. Despite his grandiose pronouncements of liberty and equality, Miranda's forces met with

little interest from the local inhabitants. He held the town for about a week before abandoning it (along with several of his disillusioned mercenaries) to the advancing Spanish royalists. Miranda returned home to his young family and a hero's welcome in London; many of his followers died in Spanish prisons. The episode later launched a bitter political controversy in the United States when opponents of Jefferson and Madison tried to tie the illegal and abortive invasion to their administration.

Miranda spent three more years in London, lobbying politicians on behalf of his cause and learning how to manipulate public opinion by prosecuting his arguments in the press. He formed close working partnerships with the philosophers James Mill and Jeremy Bentham, both of whom took a great interest in the emancipation of Spanish America. Miranda relished his position as host to the various representatives of Spanish American juntas who came to London in the summer of 1810 and returned to Venezuela himself later that year. Napoleon's invasion of Spain in 1808 had created a constitutional crisis in the empire; power legally devolved upon local town councils until the central monarchy could be restored. At first, patriotic Americans claimed loyalty to the crown, but by 1811, certain radical elements in both Buenos Aires and Caracas had come out in favor of independence and republican government. Miranda was elected as representative of the remote province of Pao when the constitutional congress was held and the First Republic declared in July 1811. He was a controversial figure, though, seen by many as old and out of touch with local realities. When the Spanish royalists staged their counterattack, Miranda reassumed his familiar role as general and commander in chief. In early 1812, he assumed emergency dictatorial powers during

the siege at Valencia, which fueled his unpopularity among the younger patriots.

Francisco de Miranda was taken in chains to the port city of Cádiz in Spain, where he lived out the rest of his days miserably in the prison of La Carraca. He continued to correspond with his friends and family, constantly beseeching them to secure his release. His health failed dramatically and he died in July 1816. Miranda was not an exceptional military talent, nor was he a gifted diplomat. Neither was he an innovative thinker. He was a master propagandist and tireless promoter of the one idea that animated his entire life: the emancipation of Spanish America. For his constant efforts on four continents, his countrymen have given him the title of Precursor.

Missionaries

For centuries, believers committed to a particular religion have endeavored to convert those with differing beliefs, and thus have affected great change throughout the world. The three main “missionizing” religions in history have been Buddhism, Christianity, and Islam.

Missionaries are men and women who propagate a particular religious belief, attempt to convert those holding a different belief, and found new communities of people to practice their belief. For at least 2,500 years, missionaries have been some of the most important agents of change in world history. In innumerable ways, missionaries have significantly shaped, and continue to shape, the world we live in today.

The definition of missionaries given above presupposes several conditions. First, the missionary’s religion is not associated with a particular village or region. That is, the religion must be transportable and not bounded geographically. It cannot be associated solely with, for example, an oracle residing in a sacred grove near an African village. Second, there is some higher authority that sends the missionary out “on mission.” Christian missionaries, for example, might receive their authority from a particular missionary society, but ultimately they believe their authority comes from God. Third, missionaries intentionally set out to try to convert others to their faith. Fourth, the missionary must believe that his or her religious belief is universally “true” and that all other beliefs are in error. This revelation needs to be shared with all nonbelievers so that they may be “liberated” from evil and falsehood. Finally, the missionary feels uniquely “called” to mission, believing that he or she has received a special commission or

mandate to bring the religious vision and its benefits to the nonbeliever.

It is also important to distinguish between “home” and “foreign” missions, although the distinctions are becoming increasingly blurred. Examples of home missionary work would include youth programs, shelters and food kitchens, door-to-door evangelizing, distribution of religious literature, public witness, and protests or pressure directed toward religious and political leaders to come more in line with specific doctrinal beliefs, such as antiabortion. Obviously, many such activities are also carried out by missionaries in “foreign” missions, which carry the religion beyond its land of origin. But foreign lands that were considered “pagan” a century ago, such as parts of Africa, are now sending Christian missionaries to the United States and Europe to convert Europeans or bring apostates back to their faith. Major world missionizing religions for at least the last two or three centuries have focused their activities not only on nonbelievers who practice local religions, such as among the Native Americans in the United States, but also on each other, such as Christians and Muslims trying to convert each other’s members. The Christian evangelical movement has targeted Central and South America for much of its missionary efforts, not toward non-Christians, but to convert the majority Roman Catholic Christian populations to Protestant versions of Christianity. While recognizing these increasingly fuzzy distinctions between home and abroad and “us” and “them,” this essay will focus primarily on missionaries working in “foreign” missions for the major world missionizing religions.

Through the notion of universality, missionaries consider their religious beliefs to be transcultural and

transcendent. The supreme power or truth that these beliefs possess overrides the nonbeliever's personal bonds with his or her immediate family, clan, ethnic identity, political organization, and local religious belief. Missionaries themselves, however, are seldom able to fully separate themselves from their own social and cultural heritage and traditions. There are some core beliefs that are essential to the faith, and therefore required of all believers in all cultures. There are other religious practices that are unique to a missionary's own national or regional (as Scotland, the Middle East) culture and heritage, and these should be modified and adapted as the religion spreads to new areas. Missionaries often link their own social, cultural, economic, and political customs, however, with the universal, core religious beliefs. Frequently these then become one and the same. Islam around the world has a distinctly Arabic nature, due in no small part to the requirement that the Qur'an be read in Arabic. Buddhism reveals its roots in Indian philosophy and culture wherever it is practiced. Chinese Confucian and Daoist concepts are closely woven into the fabric of Son and Zen Buddhism in Korea and Japan. Western Enlightenment ideas about human rights, rational thought, and the scientific method accompany many Christian missionaries. While the central religious message is universal, cultural expressions such as wearing a certain style of clothing, having only one spouse, doing "manly" work, or eating in a certain manner are often required for one to be considered a good convert to the new faith. Because of this, missionaries, such as those Christian missionaries that accompanied European imperial expansion over the last five hundred years, are sometimes viewed as cultural imperialists.

One reason for this charge of cultural imperialism is that Christian missionaries, unlike the missionaries of any other religion, have more often been involved in activities that have gone far beyond simply teaching the gospel under a tree or building a church. Jesuits served as advisers to the Chinese emperor and Japanese shogun in the 1500s and 1600s. Franciscan, Dominican, and other Catholic missionaries owned slaves in the Americas, and both Protestant and

To make potential converts feel comfortable, two Protestant missionaries in China wear traditional Chinese clothing.

Catholic missionary societies owned vast plantations and lands abroad. Besides their ministry, and sometimes instead of their ministry, Christian missionaries were involved in myriad secular activities, including establishing schools and colleges, setting up hospitals and clinics, serving as doctors, nurses, translators, interpreters, government agents, merchants, and military advisers. This involvement in local economies, governments, and cultures had an immense impact on societies and peoples around the world. To cite just one example, many newly independent countries in the second half of the twentieth century, particularly in Africa, were led by men who had obtained their primary and often higher education in Christian missionary schools, which led them to be very "Westernized" in their thinking and attitudes.

Implicit in the charge of cultural imperialism is the idea that the missionary has employed some type of force, coercion, or deception on the convert

A Spanish mission in central Mexico.

to convince him to abandon traditional ways and accept new ones. It is true that at some time in its past, every missionizing religion has been advanced through force—Islam by conquest, Buddhism by zealous feudal warlords, Christianity through the Inquisition. Still, it is also true that each of these religions recognizes that forced conversion is a counterfeit conversion, and that converts must come to their new faith with a free and open heart. The Qur'an, for example, declares, "There is no compulsion (force) in religion" (2:256).

Conversion is a major topic of study in its own right and is too complex to discuss in any detail here. But, depending on the culture in which one lives, conversion to a new religion may require the abandonment of all or large parts of one's birth culture. In many societies religion and culture and daily life are all so closely linked together that it is impossible to change one without changing all. The missionary,

who believes absolutely in the correctness of his or her vision and the benefits, such as eternal salvation, to be gained from it, will argue that each individual should be free to hear the compelling and, it is hoped, convincing message. The problem arises when the missionary has the might of imperial military and economic forces behind him or her and can call on those forces whenever necessary. When European nations and the United States, for example, forced Japan to sign "Open Door" treaties in the mid-1800s, there was generally a clause in each treaty that allowed Christian missionaries to travel anywhere in this country and proselytize freely with no restrictions. Because of the perceived threat that missionaries pose to their traditional cultures and religion, many countries with a single state-supported religion have forbidden missionaries representing other beliefs to proselytize within their borders. Many of the predominantly Roman Catholic countries in South

and Central America, for example, place restrictions on Protestant evangelical missionary activities, and Russia has placed similar restrictions on Protestants, whom they view as threatening the Russian Orthodox Church. In many Islamic countries all non-Islamic missionary activity is strictly forbidden, and conversion from Islam to another religion is punishable by death.

On the other hand, converts have often taken advantage of the missionary's connections to a wider world. For example, as more scholarly studies appear detailing Christian missionary activity during the age of European imperialism, it is clear that many nonbelievers converted less for spiritual reasons than for economic, political, or social ones. Missionaries provided chiefs with firearms, children with education, women with health care and freedom from patriarchal domination, poorer citizens with a perceived enhanced status through the opportunity to wear Western clothing, speak a Western language, and become a clerk or some other functionary in a colonial government. These self-serving motives for conversion meant that missionary successes were often quite tenuous, and there are numerous accounts of backsliders and even whole villages or chiefdoms reverting to traditional beliefs as the material or political advantages of becoming Christian changed. Missionary critics argue that even in those examples where local elites invited foreign missionaries to come and freely spread their message, there were always underlying economic or political motives that dictated this action rather than a deep spiritual commitment to the missionary's religion. It must also be said, however, that many missionaries of all faiths have been remarkable, altruistic people who truly cared for the people among whom they worked. Some fought against the harsh treatment or injustice inflicted upon local people by outside forces, such as colonial settlers, or even local governments. The priests and nuns who have been killed by dictatorships in Central America during the past thirty years represent but a few examples of this compassion and sacrifice.

No matter how or where they arrive, missionaries always meet some resistance and their chances for

success often depend on whom they are able to reach most effectively. In many cases they begin with the people at the margins—women, children, people with physical or mental handicaps, outcasts, the poor and illiterate, widows. In these instances missionaries are tolerated at best, and sometimes martyred by the elites who feel their positions threatened. When missionaries directly challenge the power elites they may be viewed as political troublemakers and their converts as traitors. Rulers in these situations may take exceptionally harsh measures against both the missionaries and converts, such as the massacre of Christians at the beginning of the Edo period (1600/03–1868) in Japan. Only in those cases where a majority of the elites and common people accept the new religion are missionaries able to initiate revolutionary change in a society. Generally, it has also been the case that missionaries are more effective among peoples who do not practice other world religions. Christian missionaries, for example, have had relatively little success in converting Muslims or Hindus.

Missionizing Religions

Buddhism, Christianity, and Islam are the three principal missionary religions in world history. In the twentieth century it was also possible to speak of missionaries for the secular belief of communism. (Although communism and the missionaries who spread it meet many of the criteria listed above, this article will discuss only religious missionaries.) But other religions have had less impact or less sustained missionary activity than these three principal religions.

Although Judaism is one of the oldest continuous world religions, it has discouraged missionary work and even conversion for many centuries. Prior to the Jewish revolts against the Romans in 66–70 and 132–135 CE, there was extensive Jewish missionary activity among certain sects of Judaism to fulfill the prophecy in Habakkuk 2:14, “For the earth will be filled with the knowledge of the glory of the Lord, as the waters cover the sea.” Following the second revolt, however, as many Jews entered the Diaspora, the focus shifted to maintaining a holy community awaiting

This table shows the extent of Protestant missionary activity of the 39 missionary societies and 1,123 missionaries active in China in 1888.

the messiah. Jewish missionary activity ceased and potential converts were even discouraged through an emphasis on strict observance of Torah (Jewish law), and by requiring male circumcision.

Some ancient religions, such as Zoroastrianism or the Egyptian cult of Isis and Osiris, claimed universal messages but were closely tied to specific sociopolitical contexts. They spread most commonly through migration, trade, war, and the conversion of neighboring peoples without the direction of any central mission authority. Many syncretic religions, such as Sun Myung Moon's Unification Church (the Moonies), the Sikhs, and the Baha'i faith have universal messages, do actively promote missionary activity, and seek converts, as do many of the myriad

independent, indigenous churches in Africa, such as the Kimbanguist Church in the Democratic Republic of the Congo.

One of the oldest and most populous religions in the world, Hinduism, with over 800 million practitioners, almost defies description because of its complexity. Because Hinduism had no founder, possesses no single creed, and looks to no single source of authority, it does not possess some of the key characteristics of a missionary religion. In the past, Hinduism essentially spread by the gradual adoption of Vedic sacred texts and practices across India and had no missionary tradition. Beginning in the nineteenth century, however, and continuing today, some "evangelical" Hindu sects, often organized around a particular

guru, have actively sought converts through missionary activities. The most well-known of these are the Maharishi Mahesh Yogi's Transcendental Meditation movement and the Ramakrishna Mission, or Hare Krishnas.

Buddhist Missionaries

“Go forth O Monks, for the good of many, for the happiness of many, out of compassion for the world, for the welfare, the good and happiness of both gods and men. Let no two of you go in the same direction. Teach the Dhamma . . . Explain both in letter and in spirit the holy life, completely fulfilled and perfectly pure” (Vinaya, Mahavagga: I.II.I).

Buddhism was the first world missionary religion, crossing boundaries of race, ethnicity, language, culture, and politics. Having given his Great Commission, the historical Buddha (Siddhartha Gautama; c. 566–c. 486 BCE), living in northern India, sent his disciples in all directions to share his teachings, the dharma. There was to be no centrally organized missionary movement, but simply individual monks and teachers going their separate ways to propagate the Buddha's teachings. The Buddha showed the way by refusing to enter into Nirvana after becoming enlightened, but living on into his eighties to teach what he had discovered through meditation and contemplation.

While Buddhist missionaries may belong to different sects, they all share a central core of beliefs, particularly the Four Noble Truths and the Eightfold Path. They do not teach that the Buddha is a deity, nor recognize any supreme god or creator. They consider the Buddha's message universal, one truth having relevance for one mankind. As there is no concept of sin in the dharma, Buddhist missionaries do not offer salvation, but rather the overcoming of, and freedom from, ignorance. They also believe that no outside spiritual force or deity, including the Buddha, can confer enlightenment. After hearing the dharma teachings, each individual must experience and realize the truth for oneself. Buddhist missionaries are unique in not competing against missionaries

from other religions. They are never to use coercion or violence to gain converts, never to try to convert someone who is content in his or her own faith, never to speak disparagingly of other faiths. Intolerance, dogmatism, and religious fanaticism are decidedly non-Buddhist-like behaviors.

Following the Buddha's death, individual monks from the monastic community, the Sangha, traveled with their alms bowls and taught the dharma along caravan routes, such as the Silk Roads, thereby linking Buddhism's spread to the development of long-distance trade. Around 262 BCE the Mauryan ruler, Asoka, adopted Buddhist principles for his vast empire. Besides commissioning the first written dharma texts, he also sent out Buddhist missionaries (monks) across India and beyond. Indian Buddhist monks brought the dharma to China in 67 CE at the emperor's invitation. By the 500s Buddhism had spread to Nepal, Sri Lanka, Vietnam, Burma, Thailand, southern China, Indonesia, and Cambodia. Ch'an Buddhism began in China around 520, and spread from there to Korea. By the 1200s, Japanese Buddhists had developed their own version of Ch'an Buddhism known as Zen. Tibet received its first Indian Buddhist missionary, the Guru Rimpoche (Padmasambhava), in 817. Ironically, when northern India came under the political control of Turkish Muslims between the ninth and twelfth centuries, many Buddhist monks were killed and their universities/monasteries destroyed. By the 1500s, Buddhism had nearly died out in the Buddha's homeland.

After several centuries of relative stagnation, Buddhism began in the 1800s to spread to Europe and the Americas. Since World War II Buddhism has gained a wide following in the West. In the 1950s and 1960s dozens of Europeans and Americans traveled to Asia where they spent years studying throughout the Asian Buddhist world. Many of them have now returned and together with thousands of recently arrived Asian immigrants have established monasteries and Buddhist societies throughout Europe and the Americas. Asian Buddhist monks now regularly visit the West to teach the dharma. Some scholars now speak of American Buddhism, which is

characterized by a unique blending of many different Buddhist practices.

Christian Missionaries

“Therefore go and make disciples of all nations, baptizing them in the name of the Father and of the Son and of the Holy Spirit, and teaching them to obey everything I have commanded you” (Matthew 28:19–20).

Matthew writes that after the Resurrection, Jesus appeared among his disciples and gave them his Great Commission. Like the Buddha, Jesus had already set a missionary example as he gathered followers, promising to make them “fishers of men” (Matthew 4:19). Following Jesus’ death, his Jewish Christian followers, based in Jerusalem, spread his message to others in the surrounding Jewish community. Whether they were one of Jesus’ original followers or new converts to his teachings, however, they remained Jews and were expected to keep the Hebrew law. It was Paul of Tarsus, recognized as the prototype and greatest of all Christian missionaries, who began to tell Jesus’ story to the Gentiles (non-Jews), and he and others carried the gospel, or good news, across Anatolia (modern Turkey) and Greece to Rome. It was Paul who separated Christianity from the Hebrew law and its Jewish context, thereby giving it a universal appeal to people of all nations.

Although there have been nearly an infinite number of schisms among Christian believers since Jesus

preached his gospel, there are still some core beliefs that a majority of Christian missionaries share. Some of these beliefs Christians adopted from Judaism, such as a belief in one God, in a messiah, or Christ, and in an afterlife. The central Christian belief is that through faith in Jesus’ sacrificial death and resurrection, individuals are spiritually and physically saved from death, their sins are redeemed, and they will return to God in heaven. All Christian missionaries will also teach that God is a Trinity, a single supreme being in three persons, Father, Son, and Holy Spirit, and that Jesus is both fully human and fully God, two natures in one.

The missionaries who followed Paul carried the gospel across the Roman Empire. A critical turning point in Christian history came when Constantine made Christianity the religion of the Roman Empire in 312 CE. Over the next seven hundred years, missionaries evangelized large parts of Europe, Ireland, Anatolia (including the important city of Constantinople [now Istanbul]), and North Africa. Much of this missionary work was undertaken by monastic monks, such as the Nestorians and Cistercians.

The second millennium began with the Great Schism of 1054, which divided Christianity between the Roman Catholic Church in western Europe and the Orthodox Church in eastern Europe and Russia. Both branches now sent out missionaries. The European Reformation that began in the 1520s gave rise to numerous Protestant sects but conflicts with the Roman Catholic Church and constant fissures and

schisms prevented them from sending out missionaries in any significant number. Meanwhile the Catholic Church dominated the missionary field, sending Dominicans, Franciscans, Jesuits, and others to the Americas, India, and Asia. Since Protestants entered the mission field in the late 1700s, Christian missionaries have encircled the globe, often accompanying Europe's imperial expansion.

While this discussion has focused on organized forms of Christian foreign missionary activity, it is also true that every Christian is expected to make public witness of his or her faith; in effect, to be a missionary. There are several statements attributed to Jesus in the New Testament that Christians believe call on them to personally spread the gospel. One such statement is found in Mark: "Go ye into all the world, and preach the gospel to every creature" (16:15). Thus, while Christian churches send missionaries abroad, members of their congregations serve the "home" mission.

Islamic Missionaries

"Invite (all) to the way of Your Lord with wisdom and beautiful preaching and argue with them in ways that are best and most gracious. For Your Lord knows the best, who have strayed away from His path" (Qur'an 16:125).

Islam is always described as a missionary religion, it has a universal message, and it has been one of the fastest-growing religions in world history. It now numbers well over a billion members worldwide. There has never been, however, a sustained and organized missionary effort in Islam to spread the message said to have been given by God to Muhammad (c. 570–632) and recorded in the Qur'an.

In the Qur'an there are many suras, or chapters, that can be interpreted as referring to missionary work. Like the earlier examples of the Buddha and Jesus, Muhammad was the first missionary for Islam. His missionary role is described clearly in the Qur'an: "O you prophet, we have sent you as a witness and a herald of good tidings, and a warner, and someone who invites people unto God by His permission, and

as an illuminating lamp" (33:45). But the Qur'an also relates that Muhammad is only the messenger, whose duty is simply to convey the message, not to convert his audience to Islam: "It is not required of you (O Muhammad), to set them on the right path but it is God who guides whom He wills" (2:272). Muhammad is to convey God's message "with wisdom and beautiful preaching," and by arguing "in ways that are best and most gracious." Through these and other verses Muslims believe that they too are obligated to share Allah's message with unbelievers. In Islam, this missionary work is known as *dawah*, and every believer is considered a missionary, whether through example or by proselytizing.

Although, as with Christianity and Buddhism, there are different branches of Islam, every Muslim would agree on certain fundamental beliefs. First among these would be the simple statement of faith: "There is no God but God, and Muhammad is his messenger." To convert to Islam, one need only recite this statement in front of witnesses. Actually, it is believed that every person is born pure and a Muslim, but some become corrupted and therefore each new Muslim is considered a "revert," having gone back to their original faith, rather than a convert. Muhammad is believed to be the last and greatest prophet of God, but not divine in any way. There will be a final judgment day and life after death in heaven or hell. A devout Muslim must also perform the Five Pillars, or duties, which include expressing the statement of faith, giving alms, praying five times a day, fasting during the month of Ramadan, and making a pilgrimage to Mecca at least once in one's lifetime.

Muhammad is said to have received his first revelations from God in 610 CE, and they continued until his death twenty-two years later. Muhammad's wife, Khadijah, was his first convert. By the time of his death Muhammad had acquired several hundred thousand followers and spread Islam across much of the Arabian Peninsula. Within a hundred years Islam was practiced across North Africa as far west as Morocco, north into southern Europe, and east to India.

While it is often argued that Islam spread by the sword (i.e., force), scholars have generally discounted this view. Rather, as Muslim armies conquered they also destroyed opposition. Islam has no clergy per se, only local prayer leaders, scholars, and holy men. Therefore Islam spread behind military conquest and through trade, following the caravan routes across North Africa and Asia, with merchants, travelers, holy men, and bureaucrats as well as soldiers carrying God's message. As they settled in new areas they established Islamic institutions, married locally, and over the decades converts appeared. Only in the past century, as Muslims have come under increasing pressure from Christian missionaries to convert, have Islamic associations, organizations, and missionary societies been formed to counter Christian efforts.

Outlook in the Twenty-First Century

Missionaries are not easily defined, as the discussion above and the examples from the three major religions illustrate. In reality, every member of every religion is a witness and example for his or her faith. Religions frequently acquire new members in ways that meet few of the conditions set out at the beginning of this essay. Islam has become the second largest religion in the world without, until very recently, any formal missionary effort. Buddhism is spread by simple monks who depend on the charity of lay believers to survive. Many religions carry out very active and passionate missionary work but their converts are few because their message does not seem to have universal appeal.

From the beginning, Christianity has combined both personal witness and intentional mission organization to spread the gospel. Over the past five hundred years Christian missionary efforts have been aided by Western colonialism and domination of technology. In 2004 there were more missionaries than ever before in world history. Christians alone have over 400,000 missionaries spreading the gospel and spend an estimated \$11 billion on foreign missions. At the end of 2009 the Church of Latter-day

Saints (Mormon Church) alone had over 50,000 missionaries serving in some 160 countries. Evangelical Christians have made it their goal to convert the entire world population to Christianity and provide "a church for every people."

And yet it appears that Islam is the fastest-growing religion today, having increased from around 400 million in 1960 to over 1.5 billion in 2009. A significant reason for this growth is the high birthrate in Asia and Southwest Asia. But Islam is also growing in the former Soviet Union, Europe, and the United States through both conversion and immigration. Buddhism is also gaining many adherents in Europe and the United States. India is experiencing a Hindu revival and many Native Americans, Africans, and other groups are recovering their traditional religions.

As the global village becomes more of a reality, the difference between home and foreign mission will lose all meaning. As transportation and communication become more accessible to the world's peoples, individuals will be able to choose their religious faith more easily than at any time in human history. A simple search on the World Wide Web reveals that in many ways, the Internet is becoming the missionary of the future. In the end, however, it will still be the single believer who brings others to his or her faith, as did the Buddha, Jesus, and Muhammad.

Mississippian Culture

At the end of the first millennium CE, the Mississippi River valley of North America was the scene of tremendous social and political transformations, resulting in the creation of what archaeologists identify as a Mississippian culture comparable to other complex societies across the globe.

The Mississippian period (c. 1000–1600) in the Mississippi River valley of North America is distinguished by characteristics found worldwide in complex societies: large population aggregations (in the case of the Mississippian culture, some verging on urban centers), monumental architecture, an intensive agricultural base, hierarchical political and social organization, ethnic diversity, and a rich array of accompanying political and religious iconography.

Commonalities

Mississippian material culture and technology, while it differed in detail, shared many similarities with other Neolithic-stage societies. Mississippians lived in large, permanent, often fortified villages that contained from a few hundred to many thousand residents. Some villages enclosed large earthen ceremonial mounds arranged around plazas and are considered specialized civic-ceremonial centers. Such centers served as the ritual and political focus for widely dispersed populations as well as being the residences of ruling chiefs and nobles. War and fertility were both important symbolically. A rich iconography involving depictions of mythic creatures of the sky and underworld played an important role in Mississippian religion.

Maize and native domesticated plants provided the primary subsistence base, but wild animals, especially fish and deer, were important supplements. Villagers hunted, fished, and fought with the bow and arrow. Chipped chert hoes and digging sticks were the main agricultural implements used to farm the large floodplain fields. Pottery manufacture and design peaked with the production of thin, shell-tempered ceramics (made from clay containing crushed clam shells) that were often painted or crafted as elaborate animal or human effigies. The vast majority of raw material needs were obtained from nearby sources. However, a limited number of materials, such as seashells, copper, and mica, were brought from distant sources for consumption by the elites.

Origins

The core geographical region of Mississippian development was the Mississippi River valley and the area around its tributaries, stretching from Illinois south to Arkansas. Mississippian societies subsequently reached north to Wisconsin, west to Oklahoma, south to Louisiana, and east to Florida. In the late nineteenth century when archaeologists first began uncovering Mississippian sites, they assumed a central origin from which subsequent migrations spread Mississippian culture across the eastern United States. During the 1960s through the 1980s Mississippian culture was reinterpreted as an ecological adaptation confined to large floodplains. In this interpretation similar societies coevolved in locations across eastern North America; the theory abandoned the notion of a central origin and migrations outward. To some degree, archaeologists have come full circle to a new

Design elements used by the Mississippian culture were both simple and sophisticated.

theory of a central Mississippian origin. This shift has been the result of new excavations and analyses at one of the earliest, most impressive and influential centers of Mississippian culture—Cahokia. Located in the American Bottom near St. Louis, this center and adjacent mound centers appear to have served as the catalyst for change across much of the midcontinent over the three centuries of Cahokia's existence (1050–1350).

The emergence of Cahokia predates all other Mississippian centers by almost a century; it is a primate center without peers. Consequently we assume its influence through population movements, religious and political ideology, and military force, all of which were pivotal for the subsequent changes we can document in subsequent Eastern Woodlands societies. These changes are related to the emergence of significant social divisions within society. Archaeological excavations have shown that the large flat-topped mounds were platforms for the homes of the leaders

and the temples of the gods. There was now a segment of society—a nobility—that was intimately associated with spiritual, political, and social power, and that was spatially segregated from those who composed the majority of the population. Nowhere was this separation more clearly indicated than in the Cahokia Mound 72 mortuaries, an elite burial ground where several burials show evidence of a ceremony that involved the sacrifice of hundreds of followers and war prisoners. Mound 72 contains a central tomb with an elite individual covered in an elaborate shell cape. He is surrounded by multiple mass graves including several that contain only the bodies of dozens of young women stacked like cordwood. One mass grave contains the bodies of men and women who have been shot with arrows, axed, and sometimes decapitated and then thrown into a pit in disarray. It is reasonable to suggest that several hundred young women and several dozen others (those violently and brutally killed) were sacrificed as part of the mortuary ceremonies that were associated with the burial of a high-ranking individual. Physical analysis has shown that the young women were less healthy and ate more corn than typical of the elite population suggesting they may have been members of the commoner populations.

Elite populations and their close kin and followers, based on the archaeology and the ethnographic record, are the primary residents of the massive ceremonial mound centers. The highest ranking individuals live in homes on the top of the flat-topped mounds. Commoner populations may live near or around the edges of such centers as well as spread across the land in small farming communities. This physical separation in living (for example commoners would not normally be allowed into the mound top temples and structures or in the inner elite precincts) is mirrored in death when the role of commoners seemed to be confined to providing the labor to build the elite mortuary mounds and the honor of being sacrificed, especially if you happened to be a wife and daughter. Commoner cemeteries are more dispersed across the landscape and there is some evidence to suggest that a portion of that population's bodies were exposed to

decay rather than buried (a common North American practice). Elite burials also included elaborate shell capes, hundreds of arrows, chunky stones (stone disks that were used in ritual games played in the central plazas of mound centers), mica, and copper.

The leaders of Mississippian chiefdoms such as Cahokia were responsible for organizing large communal feasts and celebrations of religious and political events, a major factor in maintaining group solidarity. They also enhanced and formalized intricate religious rites that included priests, temples, and a rich art that focused on aspects of life renewal, fertility, and, later, warfare. These depictions included some of the most spectacular images produced in native North American arts, such as the red stone goddess figurines of Cahokia. Very likely the same class of nobles were also the war leaders in the numerous conflicts that characterized the Mississippian period.

Cahokia

The highpoint of Mississippian culture, Cahokia, is best viewed as a regional system rather than a settlement. It contained over 120 mounds (including Monks Mound, the largest in North America) and 1.8 square kilometers of inhabited land. It was contiguous with the East St. Louis Mound group of approximately forty-five mounds and habitation areas and immediately across the Mississippi River from the St. Louis Mound group of twenty-six mounds. To put this in a broader perspective, this 13-kilometer linear strip contained three of the four largest mound centers in the Eastern Woodlands region. The archaeologist Timothy R. Pauketat has referred to this continuum of mound, plaza, and habitation zones as a Cahokian “central political-administrative complex.” It formed a corridor that encompassed 14.5 square kilometers and contained nearly two hundred Mississippian platform and burial mounds. Additionally, within 25 kilometers of Monks Mound, there were fourteen other mounded Mississippian centers in the floodplain and the uplands, half of which had multiple mounds. The majority of this monumental construction of platform and mortuary mounds, woodhenges (large circles of

posts that are thought to have ritual and calendrical uses), plazas, borrow pits, and habitation zones occurred during the eleventh to thirteenth centuries. At its height Cahokia controlled an immediate hinterland of over 9,300 square kilometers. In spatial extent and monumental construction Cahokia was equal to other early centers around the world.

Mississippian Influences

Cahokia's influence through political, social, and economic interactions with both its near and distant neighbors had a profound, but uneven, influence on the configuration of the late prehistoric cultural landscape in the Eastern Woodlands. In the thirteenth century Cahokia began to decline and warfare became more prevalent due to the concurrent rise of chiefly political organization throughout the region—a political form that typically incorporated war achievements as a primary role for male advancement in that society combined with the collapse of political and military power at Cahokia. Also at this time, new independent Mississippian centers emerged at such well-known sites as Moundville in Alabama and Etowah in Georgia. These new centers are symbolized by iconography focused on war and on elite achievement, known regionally as the

Southern Ceremonial Complex. The rise of these polities and hundreds of other smaller ones throughout the Southeast created a diverse and contentious political landscape that lasted sufficiently long to be encountered by the early sixteenth- and seventeenth-century Spanish and French explorers.

Modernity

Modernity is a vexed concept for world historians. Debates about what it means, and whether it can or should be defined in terms of western European standards, have opened the concept to a wider discussion. Especially in conjunction with the term *modernization*, such discussion considers how various peoples—Africans swept up in slave trade and the colonizers who bought and sold them, for instance—experienced modernity and were affected by it.

The concept of modernity has stimulated much debate in world history about its geographical, cultural, historical, and sociological origins. It is historically a nebulous term, extremely difficult to define, both because there is no hard and fast understanding of when the term *modernity* came into widespread use and because there is no clear-cut agreement as to what exactly it is meant to describe. Most would agree that modernity is primarily used to identify a condition of “newness”—whether in terms of an overall zeitgeist (worldview) or innovative advances in technology. Yet pinning down a defining statement of modernity, in order to gain the most complete understanding of it, requires the perspective of its historical development.

Because it is so difficult to identify how exactly modernity came into being, most treatises of the concept begin with an analysis of its etymology, followed by an examination of its cultural significance in a larger context. Many neglect, however, to reveal how tracing the origins of modernity is also to sketch the earliest foundations of the world we live in today, and to provide a more accurate understanding of the global cultural interrelationships that comprise the world.

The Origins of Modernity

Historical debate has begun to question whether or not modernity can actually be said to have had its origins in the western European Middle Ages, which dates range from about 500 CE to approximately 1492 CE. (These dates, as representative of both the beginning and the end of this period, are also in debate, since the Middle Ages can be understood and marked by different events in different cultures.) Notwithstanding this chronological variation—and despite the extremely variegated and complex history of the term as well as its influences, causes, and effects—conventional examinations of the concept of modernity locate its inception in medieval western Europe. This is as a result of the concept’s relation to two overarching developments, as Matei Calinescu describes in his seminal study *Five Faces of Modernity*: (1) the rise of an “awareness . . . of *historical time*, linear and irreversible,” which is also an “*unrepeatable time*,” profoundly related to the “Judeo-Christian eschatological view of history”; and (2) the movement, as a result of this new awareness of time, toward the inevitable comparison between the thought and achievements of the culture of Rome, or pagan antiquity, and those of the Christian Middle Ages, culminating in the late-seventeenth-century “Quarrel between the Ancients and the Moderns” (or the French “*Querelle des Anciens et des Modernes*”). Calinescu grounds his assertion regarding the origins of modernity in an etymological analysis, locating its inception in the increasing use of the word *modernus*, and identifying the foundation of the Quarrel between the Ancients and the Moderns in what he recognizes as the polemical distinction between *antiquus* and *modernus*, in

widespread use by the twelfth century (1987, 13–15). In keeping with the consciousness of a historical, unrepeatable time to which the western European Middle Ages had given rise, the Quarrel between the Ancients and the Moderns was essentially a questioning of authority. In this case, the all-encompassing cultural authority of Christianity, which had saved the European populations from the degradation and destruction following the fall of Rome, was made to give way to the authority of the cultural splendor of pagan antiquity. It is in this way, in its direct challenge to the authority of tradition, and to the authority of the ages, that the concept of modernity acquired its present connotation, as something that invariably represents the new.

Modernity and Modernization

The concept of modernity has often been confused with a companion term to which it is a very closely related—that of modernization. As the western European Middle Ages came to a close at the end of the fifteenth century and the world progressed into the sixteenth century, radical changes in cultural perspective—caused by such events as the discovery of the Americas, the advance of world trade and world travel, the rise of imperialism and colonization, new developments in scientific knowledge, the increased importance of the city, and new understandings of self and place—heralded the advent of modernization. Although it is often mentioned in tandem with discussions of modernity, modernization is much more an umbrella term for a number of sociohistorical, political, and economic changes than it is a description of an ephemeral cultural condition, as is modernity. Modernization, because it is so inextricably connected with change, is also unavoidably representative of the new. By nature of what it is, modernization thus provides the impetus and the foundation for the development and/or recognition of modernity. As the necessary side effect of modernization, then, modernity encompasses the entire range of experience produced by the socio-politico-historical and economic realities of modernization. Modernity

São Paulo's curvilinear Copan Building, built in 1951, was designed by Oscar Niemeyer, Brazil's most famous architect, and remains a monument to Brazilian modernism.

must therefore be understood, in large part, as the cultural condition arising from the dislocations and disruptions brought about by the radical changes of modernization, which is also necessarily at odds with the stasis of tradition.

Modernity: Late 1800s and Early 1900s

In the late nineteenth and early twentieth centuries, this modern movement against tradition finds an important locus in the artistic representation of the condition of modernity, as evidenced by another closely related term—*modernism*. Conventional articulations of the modern and modernism during this time refer to an artistic movement with quite specific characteristics, such as a rejection of artistic tradition, an embrace of experimental form, a fascination

with the meaning and representation of time, and the artistic rendering of the fragmented and alienating reality of modern experience. Such articulations also describe modernism as something that spans a number of western European countries, as well as the United States, manifesting itself in several artistic media, from music, dance, and literature to studio art, sculpture, theater, and architecture. Often overlooked, however, is the manner in which what was identified as “modern” (in the section above on the origins of modernity) splits in this period into two separate yet intricately related spheres. The first, objective or economic modernity, stems directly from the radical cultural change evidenced by the rise of modernization (as manifested in the nineteenth century’s Industrial Revolution and its effects on western European cultural reality); the second, is aesthetic modernity, or the exploration of the relation between objective modernity and its artistic representation. Aesthetic modernity is usually linked with the rise of French symbolism in the late nineteenth century, and its development through the period of World War I (1914–1918) and the cataclysmic alteration of western European and American cultural reality brought about by this event, to the heyday of the 1920s, and the beginnings of concentrated American involvement in the modern trend that had already swept across Europe. Despite their extreme variety and detail, however, conventional articulations of aesthetic modernity tend, if not largely to obscure, then to almost completely ignore the contributions to modern understanding of nonwhite and/or colonized peoples, women, and those outside the western European–American axis. Scholarly discourse has only just begun to address these glaring lacunae, with studies that examine the cultural contributions of these others, as well as the significance of their exclusion to our understanding of the modern. Such studies have opened up many new ways of thinking about the modern, not the least of which is to consider its meaning from new perspectives that, in producing their own versions of modernism, also reconceive more conventional notions of modernity and modernization.

Modernity: A Global Perspective

The relation between modernity and modernization also introduces a less conventional way of understanding the concept of modernity than by locating its origins in the western European Middle Ages. Although many reasons support the assertion that this geographical location is indeed the proper locus from which to derive a cultural understanding of modernity, historical debate has also begun to insist that it is too narrow a view. This becomes all the more important when considering the meaning of the concept from the perspective of world history. Understanding the significance of modernity from a global perspective requires considering what the modern might mean from a number of cultural vantage points, not just that of western Europe. What, for example, does modernity mean from the perspective of the indigenous peoples who were displaced by imperialism’s never-ending quest for new markets, or the cultural emphasis on the growth of empire? When seeking to understand the concept of modernity from a global perspective, it is important to recognize that the western European understanding of time (and therefore its relation to modernity) is not the only one, and that those developments identified as pertaining to modernization and modernity do not come to all peoples at the same time, or in the same way.

A more complex, nuanced, and accurate understanding of modernity must propose the possibility of numerous and interrelated modernities—as a means to gain a more accurate understanding of western European modernity, and as a way to open a path to knowledge regarding the meaning of modernity in other cultural contexts. For example, the rise of imperialism and the growth of empire that began in the fifteenth century, with the discovery of the Americas, led to the development of the Atlantic slave trade and the cultural involvement at different points in time of various European countries (to name just a few, first the Spanish and the Portuguese through the sixteenth century, the French in the sixteenth and seventeenth centuries, and finally the British in the eighteenth century). The millions of Africans who

were dispersed across the New World and beyond as a result of this development, and who thus came to comprise the black diaspora, did not experience modernization and modernity in the same way as did those Europeans who were the authors of imperial expansion. For Africans, modernization and modernity represented an end to autonomous cultural development, and an almost insurmountable barrier to that development, rather than the necessary and inescapable march toward an inevitable, and primarily European, progress. In this instance modernity must represent, first, a deep and painful cultural loss, and second, the long climb back to autonomous cultural life, a climb that must also take place at different points in time and in very different ways in each of the various cultural contexts in which the black diaspora was shaped.

Modernity beyond the “New”

In the early twentieth century, the disintegration of culture long held in place by tradition created a sense of almost dangerous novelty—a “newness” like nothing ever before seen or even imagined. Although other periods (such as the Italian Renaissance of the sixteenth century) also understood themselves as new and, therefore, modern, the early twentieth century seemed to many to mark an even more cataclysmic change than any that had ever come before. In the present day, however, the fantastic cultural changes of a century ago have now become commonplace, and what was once considered radically “new” is no longer a reason to marvel. In fact, the early twentieth century’s cult of the “new” has itself now become a part of our cultural tradition. How then, can modernity be understood at the dawn of the twenty-first century? What does it mean to be “modern,” once the “new” is no longer new? While such questions must necessarily remain as complicated as is the subject with which they are concerned, they are yet appropriate questions to ponder—for the consideration and impact of modernity does not, and cannot, simply end with the end of an era. Perhaps, rather than wondering whether or not our current

understanding of modernity has come to an end (as much current discourse has proposed), we must instead contemplate what it means for one era to be absorbed into another—as each understanding of the new must grow old, and each notion of modernity must be swallowed by another, more urgent articulation of the modern. What was radically new in the early twentieth century cannot enthrall the early twenty-first century. In this age beyond the “new,” modernity is more likely than not to be described in the plural, as manifest in various cultural valences, and the locus of its urgency may now be simply the fight to resolve the problem of cultural understanding and coherence in a global community.

Mongol Empire

In the early thirteenth century, an empire arose in the steppes of Mongolia that forever changed the map of Asia, enhanced intercontinental trade, and changed the course of leadership in two religions: at its height, the Mongol Empire was the largest contiguous empire in history, stretching from the Sea of Japan to the Carpathian Mountains.

The rise of the Mongol Empire began with the unification of the Mongol and Turkic tribes that inhabited the Mongolian steppes in the thirteenth century. Its immediate impact on the geography, trade, and religion cannot be overlooked, nor should its influence in later eras be ignored.

The Rise of Chinggis Khan

Temujin (c. 1162–1227), who was eventually given the honorific Chinggis Khan, emerged on the steppes as a charismatic leader, slowly gaining a following and a reputation before becoming a *nokhor* (companion or vassal) to Toghril (d. 1203/1204), the khan of the Kereits, another tribe. While in the service of Toghril, Temujin rose in power and became a major leader among the Mongol tribes. Eventually, however, Temujin and Toghril quarreled; when the quarrel came to a head in 1203, Temujin emerged victorious.

Afterwards Temujin continued to fight other tribes for dominance in the Mongolian steppe. By 1206 he had unified the tribes of Mongolia into a single supatribe known as the Yeke Mongol Ulus, or Great Mongol Nation. He reorganized Mongol social structure and dissolved old tribal lines. Furthermore, he

organized his army on a decimal system (units were organized into tens, hundreds, thousands, with the largest grouping at ten thousand) and instilled a strong sense of discipline into it. (For example, troops learned not to stop and plunder the enemy camp before victory was assured; under Temujin's rule any booty gathered before victory was declared would be confiscated.) Finally, in 1206 Temujin's followers recognized him as the sole authority in Mongolia by granting him the title of Chinggis Khan (or, traditionally in English, Genghis Khan), which is thought to mean Oceanic, or Firm, Resolute Ruler.

Expansion of the Mongol Empire

The Mongols expanded out of Mongolia, conquering Xi Xia (modern Ningxia and Gansu provinces of China) by 1209. In 1211 Chinggis Khan invaded the Jurchen Jin dynasty (1125–1234) of northern China. Initially, these were not campaigns of conquest; they were raiding activities. But as their successes grew, the Mongols began to retain the territory they plundered. Although the Mongols won stunning victories and conquered most of the Jurchen Jin by 1216, the Jin continued to resist the Mongols until 1234, seven years after the death of Chinggis Khan.

Mongol expansion into Central Asia began in 1209 as the Mongols pursued tribal leaders who opposed Chinggis Khan's rise to power. With each victory the Mongols gained new territory; additionally, several smaller states sought to become vassals. Ultimately, the Mongols found themselves with a large empire, now bordering not only the Chinese states but also the Islamic world. In Central Asia, they now bordered the empire of Khwarizm, whose

Portrait of Khubilai Khan, grandson of Chinggis Khan, the founder of the Mongol Empire.

territory included Central Asia, Afghanistan, Iran, and part of modern Iraq.

Initially, Chinggis Khan sought peaceful relations focused on trade with Khwarizm. However the massacre of a Mongol-sponsored caravan by the governor of Otrar, a city in Khwarizm, changed this relationship. After diplomatic means failed to resolve the issue, Chinggis Khan left a token force to maintain military operations in northern China and marched against Khwarizm in 1218.

After capturing Otrar, Chinggis Khan divided his army and struck Khwarizm at several points. With his army spread across the empire in an attempt to defend its cities, Muhammad Khwarizm Shah II could not compete with the more mobile Mongol army in the field. Thus he watched his cities fall one by one until he had to flee with a Mongol force in pursuit. Ultimately Muhammad died from dysentery on an island in the Caspian Sea. Although his son, Jalal ad-Din, attempted to defend what is now Afghanistan, Genghis Khan defeated him near the Indus River in 1221, forcing Jalal ad-Din to flee to India.

Although he destroyed Khwarizm, Chinggis Khan kept only the territory north of the Amu Dar'ya River so as not to overextend his army. Meanwhile, he returned to Mongolia in order to deal with a rebellion in Xi Xia. After resting his army, he invaded Xi Xia in

1227 and besieged the capital of Zhongxing. He died during the course of the siege but ordered his sons and army to continue the war, which they did.

The Mongol Empire after Chinggis Khan

Ogodei (1185–1241), Chinggis Khan's second son, ascended the throne in 1230. He continued operations against the Jin and successfully conquered it in 1234. Mongol forces also invaded Iran, Armenia, and Georgia during Ogodei's reign, bringing those regions under control. Meanwhile, a massive force marched west, conquering the Russian principalities before invading Hungary and Poland. While they did not seek to control Hungary and Poland, the Mongols left both areas devastated before departing, possibly due to Ogodei's death in 1241.

Ogodei's son Guyuk (d. 1248) came to the throne in 1246 only after a lengthy succession debate. In the interim, Guyuk's mother served as regent. Guyuk died two years after taking the throne; his wife then served as regent, but did little to assist in choosing a new khan, which led to a coup in 1250 by Mongke (1208–1259), the son of Chinggis Khan's fourth son. During his reign Mongol armies were once again on the march. He and his brother Khubilai (1215–1294) led armies into the Southern Song dynasty (1127–1279) while Hulugu (c. 1217–1265), another brother, led an army into the Middle East.

In 1256 Hulugu's forces successfully destroyed the Ismailis, a Shiite group in northern Iran. He then moved against the Abbasid caliphate in Baghdad. The caliph, nominally the leading religious figure in Sunni Islam, refused to capitulate but did little to defend the city. The Mongols sacked Baghdad and executed the caliph in 1258, ending the position of caliph for several centuries. Hulugu's armies also invaded Syria, successfully capturing Aleppo and Damascus. Hulugu withdrew the bulk of his army in 1259–1260, however, after receiving news that Mongke had died during the war against the Song. Meanwhile, the Mamluk sultanate of Egypt struck the Mongol garrisons in Syria and defeated them at

Ayn Jalut in 1260. The Mongol Empire spiraled into civil war after the death of Mongke, and Hulugu was never able to recover the Syrian conquests for the long term, as he was preoccupied with his rivals in the rest of the empire.

Khubilai eventually prevailed (in 1265) in the civil war, but the damage to the integrity of the empire was great. While the other princes nominally accepted Khubilai as the leader of the empire, he had very little influence outside Mongolia and China. Khubilai and his successors, known as the Yuan dynasty (1279–1368), found their closest allies in Hulugu and his successors. Hulugu's kingdom, known as the Il-Khanate of Persia, dominated the territory of present-day Iran, Iraq, Turkey, Armenia, Azerbaijan, and Georgia. Central Asia was ruled by the descendants of Chagatai (d. 1241), Chinggis Khan's third son. Meanwhile in Russia and the Russian steppes, descendants of Jochi (d. 1225?), Chinggis Khan's first son, held power. Their state became known as the Golden Horde.

The Mongol Empire in World History

The impact of the Mongol Empire on world history is incalculable, especially in geography, trade, and religion.

Geography

In terms of geography, both physical and human, the Mongol expansion forever changed the face of Asia. The change began in Mongolia. Prior to the Mongol Empire, the inhabitants of that region were members of many disparate tribes. Under Chinggis Khan, all of the tribes were united into one new collective unit. Furthermore, tribal identities were stripped away as old tribal elites were dispensed with and a new social organization was forged that focused on the family of Chinggis Khan. The Mongolian nation of the modern era exists today because of the rise of the Mongol Empire. Chinggis Khan also unified the Mongol tribes through the imposition of a written language. Having seen the value of writing among the Naiman, one of the tribes he defeated in 1204, Chinggis Khan ordered that a Mongolian script be instituted. This script was adapted from the Uygur script, itself based on Syriac, brought east by Nestorian Christian missionaries. It remained in use in modern Mongolia until the twentieth century, when it was replaced with a Cyrillic script; it is still in use in the Inner Mongolian Autonomous Region of China.

The Mongol expansion also caused the movement of other tribes, primarily Turkic. While some moved into Hungary and the Balkans, as well as Syria, many

moved into Anatolia (modern-day Turkey). A strong Turkic presence existed in Anatolia since the eleventh century, but the new influx of Turks eventually led to the Turkification of the region. One of the groups that moved into the region was the Osmanli, who established the Ottoman Empire in the fifteenth century.

Other groups also emerged from the Mongols. Later Turkic peoples, such as the Tatars of Crimea and Kazan, the Kazakhs, and the Uzbeks, trace their origins to the Mongols who settled the territories of the Golden Horde. The Tatars were direct offshoots from the collapse of the Golden Horde in the later fifteenth century. The Uzbeks, named after a ruler of the Golden Horde during its golden age, also came from the Golden Horde. The Kazakhs split from the Uzbeks and remained a primarily nomadic people until the twentieth century, whereas the Uzbeks settled in the more urban areas of Central Asia in the sixteenth century. For a brief period they established an empire that was a contemporary of the Ottoman, Safavid, and Mughal empires. The Mughal Empire itself gained its name from the Persian word for Mongol. Its founder, Babur (1483–1530), was a descendent of the Central Asian conqueror Timur (1336–1405), who traced his lineage back to Genghis Khan.

While new groups were formed from the Mongol armies and the Mongol invasions set off a number of migrations of nomads across Eurasia, the Mongols also caused a tremendous amount of destruction. Although much of the data in the sources concerning the number of people killed during the Mongol conquests is exaggerated, those exaggerations do reflect the reality that thousands died, and the Mongols were not above depopulating an area if it suited their purpose.

Trade

From the beginnings of the Mongol Empire, the Mongol Khans fostered trade and sponsored numerous caravans. The very size of the Mongol Empire encouraged the wider dissemination of goods and ideas throughout Eurasia, as merchants and others could

now travel from one end of the empire to another with greater security.

The fact that virtually a whole continent was under one rule helped make it possible for inventions such as mechanical printing, gunpowder, and the blast furnace to make their way west from China. In addition, commodities such as silk could be purchased at lower prices because cost of travel and security decreased thanks to the Pax Mongolica afforded by the Mongol Empire. Artistic ideas, sciences such as astronomy, and medicinal ideas also traveled back and forth. China, for its part, was enriched by outside influences in art, theater, and by advances in science and medicine as well.

Religion

The central importance of Chinggis Khan in the Mongol Empire cannot be ignored. As descent from Chinggis Khan became a key component in establishing one's right to rule throughout much of central Eurasia, it had a considerable impact on rulers. Russian princes in Muscovy and Central Asian rulers alike often forged their genealogies to connect themselves to Chinggis Khan, much as some Muslims forged genealogies to connect themselves to the Prophet Muhammad. In Mongolia, the principle of descent from Chinggis Khan had a dramatic impact on religion.

Virtually all of the elite in Mongolia could trace their lineage back to Chinggis Khan, which made it difficult for one prince to assert primacy over others and become the leader of the majority of the Mongols. Thus, princes had to find other ways of legitimizing power. Altan Khan (1543–1583) did this by establishing ties with the leader of the Yellow Sect in Tibetan Buddhism, who was bestowed with the title of Dalai Lama, and, with the aid of Altan Khan, became the preeminent figure in Tibet. This courtship of Buddhist figures also led to the conversion of Mongolia to Buddhism in the sixteenth century.

The Mongols' destruction of the Abbasid caliphate had significant consequences for religion as well. The caliph was meant to be the spiritual, and, if

possible, political leader of the entire Islamic world, although even prior to the rise of the Mongols, this was an ideal more than a reality. After the Mongol conquest, although several rulers maintained the presence of a puppet caliph, the institution was not revived with any credible authority until the nineteenth century, when the Ottoman sultan also served as the caliph. The result was a decentralization of Islamic authority in the centuries following the defeat of the Abbasids.

Further Implications

The establishment of the Mongol Empire in many ways marked a crossroad in world history. As the largest contiguous empire in history it united Eurasia in a fashion that has not been repeated. Actions within the empire inevitably rippled across the rest of Asia and Europe, whether through trade, warfare, or religious affairs. Furthermore, because it ended several previous dynasties and instigated the creation of new power centers, the Mongol Empire may be viewed as a catalyst for significant geopolitical change.

Moses

(C. 13TH CENTURY BCE)

HEBREW PROPHET AND LEADER

Moses, the Hebrew prophet and leader, figures prominently in biblical accounts of his people. Yahweh, the Hebrew God, charged Moses with freeing the Hebrews enslaved in Egypt and leading them to Canaan, the land promised to their ancestors. Moses also consulted Yahweh and instituted the Decalogue and Covenant Code, both of which would prove to be major elements in establishing the Israelites' culture and religious practices.

The prophet Moses, leader of the Hebrews and one of the Bible's most renowned figures, began his life in Egypt during a difficult time for his people. The reigning pharaoh, who some scholars suggest may have been Ramses II or Seti I, felt that the Hebrew populace had become too large and decreed that every Hebrew male child be killed at birth. Moses was born in the midst of this compulsory genocide, but with the aide of his sister, the pharaoh's daughter, and two defiant midwives, he survived. Three months after his birth, Moses' mother crafted a papyrus basket and plastered it with bitumen and pitch. She then carefully placed Moses and the basket in the Nile River; his sister stood at a distance to watch what would happen. The daughter of the pharaoh saw the floating container and had her maid bring it to her. After discovering the child, she took pity on him, and requested that a Hebrew woman come and serve as his nurse. Ironically, the woman chosen for this task was Moses's mother. Moreover, she was able to rear

him in the household of the pharaoh who desired to kill him.

This special birth motif is a common theme in stories found throughout the Near East and in cultures around the world. The theme often introduces people, primarily men, who amazingly avoid death during their infancy or are born miraculously to mothers who are barren. Subsequently, the children become great leaders. One example of note from the neighboring Mesopotamian culture is the legend of Sargon. According to Akkadian writings, the mother of Sargon of Agade also made a basket sealed with pitch after the birth of her son. She placed the infant in the basket and let it sail down the Euphrates River. Akki, the drawer of water, discovered baby Sargon and reared

A drawing of Moses copied from the catacombs at the Basilica of St. Agnes outside Rome.

Let me tell you something that we Israelis have against Moses. He took us 40 years through the desert in order to bring us to the one spot in the Middle East that has no oil! • Golda Meir (1898–1978)

Sir Lawrence Alma-Tadema, *The Finding of Moses* (1904). Oil on canvas. Alma-Tadema was renowned for fanciful representations of classical antiquity. In this painting, which depicts a caravan carrying Moses in his papyrus basket from the Nile, the artist included archaeologically precise details and inscriptions.

him; the goddess Ishtar protected him, and Sargon became a successful king.

Although Moses did not become a king, he lived his youthful years in the home of the ruling pharaoh. Here Egyptian teachers educated him, and he learned the intricacies of Egyptian culture. However, the biblical writers explain that Moses was very much aware of his Hebrew ethnicity. For example, he murdered an Egyptian whom he saw beating a fellow Hebrew. But because someone witnessed his crime, Moses had to leave Egypt immediately in order to save his life.

Shortly after his departure, he encountered Yahweh, the Hebrew God, for the first time. He was now married to Zipporah, the daughter of Jethro, a Midianite priest. While walking his father-in-law's flock on Mt. Sinai, he witnessed a bush that burned without

being consumed. Yahweh spoke to Moses from the bush and charged him to return to Egypt, liberate the Hebrews, and lead them to a land that had been promised to their ancestors.

With the assistance of his brother Aaron, Moses confronted the pharaoh regarding the release of the Hebrews. The process was taxing, as the pharaoh refused his numerous requests. Thus, the writers describe how Moses, with the hand of Yahweh, instituted ten plagues, some of which brought darkness upon the land, a cacophony of frogs, locusts, excruciating boils, and damaging hail. However, the tenth and final plague, the death of all of the Egyptians' firstborns, was the zenith of this battle of wills. This act, without question, reflects the Hebrew genocide that Moses narrowly escaped during his birth. There

Domenico Feti, *Moses before the Burning Bush* (1613–1614). Oil on canvas.

are continuing scholarly debates regarding the exodus from Egypt, the route(s) taken, and the famous parting of the sea, but most agree that the event would have happened at the Red Sea.

Once the Hebrews safely left Egypt, Moses and Aaron began their trek to the Promised Land. The journey led them through the wilderness for forty years. During this time, there were problems with apostasy, grumblings regarding the conditions during the journey, and disagreements among the leadership. Yet Moses consulted Yahweh and instituted the Decalogue and Covenant Code, both of which would prove to be major elements in establishing the Israelites' culture and religious practices. Sadly, the brothers were not permitted to enter the Promised Land. Nevertheless, Moses—as the prophet, the liberator, and

Domenico Beccafumi, *Moses and the Golden Calf* (1536–1537). Oil on wood. Duomo, Florence.

the spiritual leader—is responsible for the Hebrew Exodus and the victorious trek to Canaan. There are no contemporary extra-biblical writings that reference Moses or the Exodus. But most scholars argue that the biblical sources are well constructed and that later authors would have been unable to create such an individual as Moses.

Motecuhzoma II

(1467–1520)

EMPEROR OF PRE-SPANISH MEXICO

Motecuhzoma II was emperor of the Triple Alliance (Aztec Empire) at the time of the Spanish conquest of Mexico. Although a strong king with numerous accomplishments, Motecuhzoma II has been burdened with an undeserved reputation as a weak and ineffectual opponent to the conquering Spaniards.

When the Spanish conquistador Hernán Cortés came to Mexico in 1519, Motecuhzoma II was the emperor of the Triple Alliance (Aztec Empire). Born in 1467 into the royal family of Tenochtitlán, the dominant city in the alliance that ruled the empire, Motecuhzoma II was called Motecuhzoma (Angry Lord) Xocoyotzin (the Younger) to distinguish him from his great-grandfather, the king Motecuhzoma Ilhuicamina (An Arrow Pierces the Sky), also known as Motecuhzoma I.

Succession in the Tenochtitlán dynasty passed among male members of the royal family as determined through election by a royal council upon death of a king. By 1502, when the emperor Ahuizotl died, his nephew Motecuhzoma II (grandson of the emperor Axayacatl) had distinguished himself in battle and was an obvious choice for the throne. Native historical accounts are unanimous in their praise of Motecuhzoma II's qualities. For example, the *Codex Mendoza* (a postconquest history written in the ancient style) describes his "bravery and leadership in war" and goes on to describe him as follows: "Motecuhzoma was by nature wise, an astrologer, a philosopher, and skilled in all the arts, civil as well as military. His subjects greatly respected him because of his gravity, demeanor, and power; none of his predecessors, in comparison, could approach his great

state and majesty" (Codex Mendoza, folio 14 verso; Berdan and Anawalt 1992, vol. 4:34).

During his reign (1502–1520) Motecuhzoma II led wars of conquest to consolidate the distant provinces of the empire. He worked to concentrate power in the hands of the top nobility at the expense of commoners. Whereas Ahuizotl had permitted talented commoners to occupy important offices, Motecuhzoma stripped these commoners of their titles and decreed that only members of the top nobility could hold high office. Nigel Davies calls this "a definite step in the direction of an absolute monarchy" (Davies 1973, 216). He also carried out a series of religious and calendrical reforms to help claim supernatural support for his political agenda.

In 1519, Hernán Cortés and a band of several hundred Spaniards landed in Mexico. Motecuhzoma did little to fight the Spaniards, who were able to enter Tenochtitlán without opposition. Cortés took the king hostage, and he was soon killed. Native sources state that the Spaniards killed Motecuhzoma, whereas Spanish sources state that he was killed by an Aztec mob that was assaulting the palace where he was held.

One of the central "mysteries" of the Spanish conquest of the Aztecs is Motecuhzoma's failure to oppose Cortés more vigorously. Why did the king not send his armies—with tens of thousands of experienced troops—to fight Cortés? One interpretation blames the Aztec king for indecisiveness and vacillation. According to this view, the king was frozen in uncertainty and therefore permitted Cortés to enter Tenochtitlán unopposed. This popular view of Motecuhzoma as an indecisive and weak leader, however, is contradicted by his history as emperor between 1502 and 1519.

Antonio Rodriguez, *Portrait of Motecuhzoma II* (c. 1680). Museo degli Argenti, Florence, Italy.

According to recent scholarship, indigenous nobles and Spanish Franciscan friars in the decades after the conquest conspired to invent reasons for Motecuhzoma's hesitation. One such reason was the dubious notion that Motecuhzoma believed Cortés to be the god Quetzalcoatl returning to reclaim his kingdom. A related reason was a series of omens throughout his reign that supposedly alerted Motecuhzoma to his impending doom. These stories "explained" Motecuhzoma's behavior and allowed the surviving colonial-period Aztec nobility to make sense of the conquest. These stories also helped the Spanish friars promote the notion that the conquest was preordained by God in order to bring Christianity to the New World. Many authors of works about the conquest of the Aztecs—particularly the influential books by Prescott (2000; first published in 1843) and Thomas (1993)—have accepted these stories at face value. Revisionist scholarship, however, indicates that these stories were myths invented in the sixteenth century, and identifies other factors that explain Motecuhzoma's actions in a more satisfactory fashion.

The actions of Motecuhzoma in fact indicate that he followed the advance of the Spaniards closely and attempted to have his subjects defeat them along the way (most notably at Cholula, where a planned ambush turned into a massacre of Aztec troops). He ultimately let the Spaniards into Tenochtitlán only as a last resort after recognizing their huge military and technological superiority. In Aztec diplomacy, a ruler who submitted peacefully to a conquering army secured a lower tribute quota and milder treatment for his people than a ruler who openly opposed the imperial troops. Motecuhzoma's failure to oppose Cortés more vigorously may have arisen from an attempt to secure better treatment for his subjects under the Spanish crown. Regardless of the actions of Motecuhzoma, however, the final Aztec defeat was assured by the introduction of smallpox and its devastating effects on the native population.

Mountains

Mountains evolved as havens of bio- and cultural diversity and have long been associated with indestructibility, ruggedness, and characteristics hostile to human endeavors. Until the U.N. designated 2002 the International Year of the Mountain, environmentalists ignored the fragility of mountain regions. Poor, indigenous mountain peoples, victimized by central governments, often have little choice but to overexploit their environment, and are threatened by warfare ubiquitous in many mountainous lands.

The word *mountains* may conjure up an image of gigantic rock precipices, sharp peaks, glaciers and snow—and a team of grim-faced mountaineers, roped together, risking avalanches, rock falls, and blizzards in their arduous upward progress—the sort of scene one might see in the upper sections of the Alps or the Himalayas, or in the many other dramatic high landscapes of the planet. But that scene represents only a small fraction of our mountain environment. While there has been much debate among academics over how to define *mountain*, no simple statement has evolved. The people of Wales and northwestern England would insist that they live among mountains, yet their highest summits barely exceed 1,000 meters (about 3,280 feet) above sea level. Nomads of Tibet or agricultural peasants of southern Peru who live 4,000 meters (more than 13,120 feet) above sea level would be classified as mountain folk, yet their local landscapes may be as flat as the North American prairies.

Nevertheless, a varying combination of high altitude and steepness of slope make for short growing seasons and slow soil formation processes. The

variation in average annual temperature with altitude and latitude has combined to give the Lofoten Islands of North Norway, close to sea level and 70° north, and the upper reaches of the Swiss Alps, above 2,000 meters and 46° north, similar landscapes, referred to as “alpine.” Both are above the limits of tree growth (timberline) and have been molded by glaciers. In contrast, locations at high altitudes (above 3,500–4,000 meters, or roughly 11,500–13,120 feet) that are close to the equator, such as in Ethiopia, Kenya, or Ecuador, with rather rounded landforms, may support flourishing agriculture. Carl Troll (1900–1975), the famous German mountain geographer of the twentieth century, remarked that above 3,000 meters (about 9,850 feet) in Indonesia, for instance, there are high mountains without a high mountain (alpine) landscape.

In its efforts to ensure a critical assessment of the importance of mountains to sustainable human progress, the United Nations adopted a pragmatic approach in its declaration of 2002 as the International Year of Mountains (IYM), claiming that mountains occupy about 20 percent of the world’s terrestrial surface and provide the direct life-support base for about 10 percent of humankind. Indirectly, in terms of their resources, such as provision of more than half of all fresh water, forest products, minerals, grazing lands, and hydropower, mountains are vital to the survival of over 50 percent of the total population. Furthermore, mountains have provided the spiritual essence of all major and many minor religions. Second only to coastal areas, they are the major focus of tourism, the largest and most rapidly expanding industry in the world. Mountains shelter some of the world’s most important centers of biodiversity

People living near the Pamir Mountains in Tajikistan call them both “the roof the world” and “the feet of the sun.” Photo by Jack D. Ives.

and a large share of its cultural diversity. Finally, climate change, especially the currently anticipated global warming, would have some of its earliest and most noticeable effects in mountain regions. It follows that mountains are becoming a serious object of concern.

Geographical Distribution of Mountains

Mountains are found on every continent, from the equator to the poles as far as land exists. Taken together as a single great landscape category or ecosystem, they encompass the most extensive known array of landforms, climates, flora, and fauna, as well as human cultural diversity. From a geological and tectonic point of view they comprise the most complex of the Earth’s underlying structures.

Mountains and uplands incorporate the inhuman and extremely cold and sterile high ice carapaces of

Antarctica and Greenland as well as the high, dry, hypoxic, and almost uninhabitable ranges of Central Asia and the south central Andes. They also include richly varied and even luxuriant ridge and valley systems of the humid tropics and subtropics, such as the eastern Himalayas, the Hengduan Mountains (Yunnan, China), Mount Cameroon, sections of the northern Andes, and parts of New Guinea. In east Africa and Ethiopia, the flanks and valleys of the high mountains have long been the preferred human habitat compared with the arid lowlands that surround them. An enormous array of other mountains must be included—for instance, the high volcanoes of the Caribbean and Central America, Indonesia, Japan, and Hawaii, where humans have long benefited from access to rich soils regardless of exposure to extreme fiery hazards. So-called middle mountains (German: *mittelgebirge*) range from Tasmania to South Africa and from central and northern Europe to the Urals and Siberia. While the Urals contrast with the Alps

Multiple hand-built terraces and rice paddies in the Nepal Middle Mountains east of Kathmandu are a remarkable feat of engineering; the irrigation system demonstrates how indigenous peoples prove to be outstanding soil conservationists. Photo by Jack D. Ives.

(the epitome of “high mountains,” German: *hochgebirge*) because of their more subdued relief, their other mountain attributes warrant special policies to ensure sustainable resource use and preservation of their traditional landscapes.

The high mountains of the world are associated with the most recent, or Tertiary to present, geological period of mountain building resulting from movement of the Earth’s tectonic plates. This has established two great systems of mountain ranges: the circum-Pacific and the transverse Atlas-Pyrenees-Alps-Caucasus-Hindu Kush-Himalaya-Indonesian arc. Collectively they form the loci of most of the world’s active volcanoes and the majority of seismic epicenters (earthquakes). Mountains are dangerous places to live, given the combination of gravity, steep slopes, often very high levels of precipitation, tectonic disturbance, and volcanic activity. Many mountain regions are also dangerous because of the actions of people.

Changing Attitudes Toward Mountains

Try to picture the classical image of a mountainous landscape: the physical characteristics, together with relative inaccessibility and remoteness from the mainstreams of world society, provide images of indestructibility, ruggedness, and hostility to most human endeavor. Yet these same characteristics over a long timeframe have led to unparalleled biodiversity and cultural diversity. Mountain communities evolved in semi-isolation, developing and preserving local languages, costumes, customs, and intricately adapted farming and grazing practices. They frequently retained high levels of independence. The independence of mountain communities, however, was bought at a price: hard physical labor for survival, the risk of natural hazards, and periodic forced out-migration as population growth depleted local resources.

A young Lisu woman, a member of a hill tribe living in northern Thailand. Photo by Jack D. Ives.

Many mountain communities became famous as providers of fiercely effective mercenaries for the national armies of lowland powers. For example, the Swiss mountain contingents contributed to many pre-modern European armies, a surviving remnant being the Vatican's Swiss Guard. More recently, during two world wars and the Falkland Islands campaign, the Gurkhas of Nepal won international fame. They continue to supply contingents to the Indian and British armies.

Prior to the early twentieth century, remoteness, lack of "modern" communication links, and low population densities led to mountain regions being established as buffer zones with only roughly surveyed frontiers between powerful lowland-based empires. Those imperial conflicts and compromises left many present-day states with irrational frontiers, such as those possessed by Afghanistan—a nineteenth-century product of the rivalry between the British Empire and imperial Russia. This has frequently led to major political and military problems and insurgencies for

which the world as a whole is paying a disastrous price today.

As far as the affluent West was concerned, until the last decades of the twentieth century, mountains were virtually the preserve of mountaineers and tourists, especially winter-sport enthusiasts and warmer-season trekkers, and a relatively small number of scientists. The people who lived and made their livelihood in the mountains were largely ignored.

In Europe, as nations industrialized and modernized during the nineteenth century, roads and railways were built, and the first waves of affluent tourists and mountaineers began to penetrate the Alps, bringing with them money. In the twenty-first century we think of Switzerland and Austria as regions of great wealth, but national government policy recognizes that mountain agriculture, essential to the conservation of the beauty that makes the mountains a tourist attraction, depends upon heavy subsidy. In this sense a broad division can be made between the development of mountain regions in the

Climb the mountains and get their good tidings. • John Muir (1838–1914)

industrialized countries and those of the developing world—the difference being that industrialized countries have money to help preserve the scenic nature of the mountains whereas developing countries focus on exploitation. A further subdivision must be made between mountain regions of the Old World (Europe) and those of the New World (the North American West, New Zealand, and Australia). In contrast to the European Alps, for example, that have a very long history (pre-Roman) of settlement and environmental adaptation, mountain regions of the New World have experienced colonization and development only very recently (from about the mid-nineteenth century).

Globalization has spread mass tourism from industrial countries into selected areas of the mountain regions of developing countries. Where tourism, especially mountaineering and trekking, has selectively penetrated parts of the developing world's mountain regions, it has brought about significant change. Tourism does bring increased wealth, but very selectively, and most of the commercial profits go back to the industrialized countries as investment profits. The recent, similar “moneyed” approach of nouveau riche Chinese entrepreneurs is having a parallel impact on “within-country” regions, such as northern Yunnan Province in China's scenic southwest

Tourism can and has caused serious disruption to local cultures. (The outstanding example is the Mount Everest region of Nepal, whose inhabitants, the Sherpas, have become relatively affluent.) The 1970s and 1980s recognized the growing need to preserve the Alps and to avert (perceived) imminent environmental catastrophe in the Himalayas. In the Alps, uncontrolled growth of two-season tourism threatened the traditional mountain landscape, although staunch Swiss and Austrian democratic processes have tempered that threat. In the Himalayas massive deforestation was blamed on “ignorant” mountain subsistence farmers; their rapid population growth (Nepal, for instance, at 2.7 percent per year) and their dependency on the forests for construction materials, firewood, and fodder, led to the assumption that the (perceived) impending environmental collapse was due entirely to imprudent indigenous land use on the

mountain slopes. Furthermore, increased numbers of landslides and acceleration of soil erosion, influenced by gravity and torrential monsoon downpours, was widely believed to cause downstream siltation and an increase in severe flooding in Gangetic India (the region formed by alluvial deposits of three great river systems, including the Ganges), and in Bangladesh. Thus the potential for international dispute was added to the threat of environmental disaster. Regardless, prior to 1992 concern remained limited.

Why, as recently as the 1970s or even the 1980s, were mountains not afforded a more prominent place on the world's political agenda, when environmental movements had been in full swing for some time? A partial answer is that mountains had not yet attracted an effective constituency. During the 1972 U.N. Stockholm Conference on the Environment, great strides were made in recognizing the growing gap between the have and have-not regions of the world and by the establishment of ministries of the environment in numerous member countries. Yet mountains did not even merit a footnote. It was not until the 1992 United Nations Conference on Environment and Development (UNCED; the Rio de Janeiro Earth Summit) that a real breakthrough appeared possible with the inclusion of a special chapter for mountains in Agenda for the 21st Century (Agenda 21), the summit's plan for fostering governmental and individual sustainable action. Chapter 13 (which deals with managing fragile ecosystems and sustainable mountain development) of Agenda 21 led ten years later to the U.N. General Assembly's designation of 2002 as the “International Year of Mountains.”

Problems Facing the World's Mountains

Undoubtedly, mountains are threatened by general overuse of natural resources—water, forests, grasslands, and minerals—that can lead to soil erosion, water and air pollution, and downstream damage. This is particularly severe on steep slopes (as compared with regions of gentle relief). Indiscriminate road construction on unstable slopes and erection of

A Tibetan lady holds a bunch of radishes (1979). Tibetans who live 4,000 meters above sea level would be classified as mountain folk, yet their local landscapes may be as flat as the North American prairie. Photo by Jack D. Ives.

high dams, usually for the sole benefit of downslope communities, are aggravating factors. Unregulated mass tourism can also lead to environmental degradation, loss of biodiversity, disruption of mountain cultures, and an augmented sense of deprivation as well as actual deprivation on the part of many poor mountain people. These are the topics that hit the news headlines. But they are frequently overdramatized. Too often the causes, as outlined in the case of the Himalayas, are misunderstood, oversimplified, or even falsified for political advantage. In any case, mountain communities, whether they are in the Alps or in the Himalayas, are in economically marginal positions compared with their lowland counterparts. A large proportion of the world's poverty, especially in Asia and South America, is located in mountain regions. It is difficult to make a precise statement because demographic and related data are usually aggregated by their inclusion into larger political survey units, so that specific information is unobtainable.

The entire complex of mountain problems has been further exacerbated by an apparent unwillingness, until very recently (principally after the terrorist attacks of September 11, 2001), to publicize the single most devastating process that is occurring within mountains: warfare in all its forms. This includes conventional armed conflict, guerrilla insurgencies, drug wars, and terrorism. Moreover, mistreatment of mountain peoples has caused a great increase in the number of internal and international refugees. The U.N. Food and Agriculture Organization (FAO) claimed during the launch of the IYM on 11 December 2001 that of the twenty-seven wars affecting the world at that time, twenty-three were located in mountains regions. This disproportionate burden that the mountains and their people carry signals real disaster—human, economic, environmental, political—on an unprecedented scale.

In terms of overall conflict, mountain peoples are frequently victimized by the central governments. In northern Thailand, western China, and the

Himalayan countries, they are unfairly and wrongly blamed for catastrophic environmental degradation. The real culprits are frequently large commercial interests intent on resource exploitation and central governments seeking access to resources at the expense of the local people who are often marginalized minorities with little political clout. Nevertheless, poverty often leaves the local mountain people with little alternative but to overexploit their own environment. Regulations, such as logging bans, are imposed by the bureaucracies in the lowlands, and they often lead to unsatisfactory solutions that may further exacerbate mountain poverty, thus generating further unrest. This acute dissatisfaction has erupted over the last decade into widespread insurrections in many of the world's mountain regions, from Pakistan, Nepal, and northeast India to Colombia and Bolivia.

Future Directions

The vast extent of the world's mountainous territory, together with its extreme complexity, both in terms of the inherent natural phenomena and the innumerable ways in which human communities have adapted to them, are a challenge indeed to sustainable development. Mountains as a whole are among the least known and least understood areas of the world. The International Year of Mountains has provided an unprecedented opportunity for expanding research and for rapid growth in communication. This has combined with the growing awareness that many of the forecasted negative aspects of global warming will have early major and accelerating impacts in mountain regions. Such concern has resulted in an enormous upsurge in interdisciplinary and international

research collaboration, the expected results of which await future application. The first task, however, is to reduce the burden of conflict and, related to this, to facilitate involvement of mountain people in management of their local resources and in development of relations with society at large.

Mughal Empire

During its peak the Mughal Empire (1526–1857) flourished as a result of a strong centralized government, an increase in trade, and the rise of new markets in urban centers such as Delhi, Agra, Lahore, Dhaka, Surat, and Masulipatnam. Indo-Islamic architecture reached its apogee under the empire, with opulent palaces, tombs, forts, mosques, and gardens.

The Mughal Empire ruled the area of present-day Afghanistan, Pakistan, and much of northern India from 1526 until the official defeat of its last ruler, Bahadur Shah II (1775–1862), by the British in 1857, though its true decline dated from the death in 1707 of Aurangzeb (1618–1707), the last of the great Mughal emperors. The years of Mughal preeminence saw extraordinary developments in art, architecture, civil administration, and efforts at religious tolerance.

Establishment and Golden Era

Babur (1483–1530), the ruler of Fergana in present-day Uzbekistan, founded the Mughal Empire when he defeated Ibrahim Lodi, the ruler of the Delhi sultanate (1192–1526), in the first battle of Panipat in 1526. With Delhi under his control, Babur proceeded to vanquish the Rajputs of central and northern India, and the Afghans. Babur's successor Humayun (1508–1556) was not able to check Sher Shah (1486–1545), the powerful Afghan ruler of Bengal (present-day Bangladesh and northeastern India), and after defeat in the battle of Chausa in 1539, Humayun took asylum at the court of Persia. Humayun eventually returned to power but ruled for just a year before dying. He was succeeded by his son Akbar (1542–1605), one of

the greatest kings of India, who ascended the throne in 1556. Akbar cemented relations with the Rajputs through matrimonial alliances while defeating recalcitrant rulers, and he overhauled the administration of the empire. His major contribution was his policy of religious eclecticism—an enlightened vision of religious tolerance.

Akbar bequeathed his son Jahangir (1569–1627) an empire stretching from Kabul in the northwest, Kashmir in the north, Bengal in the east, and beyond the Narmada River in the south. Jahangir's reign was marked by political conspiracies; his queen, Nur Jahan (d. 1645), was the true power behind the throne from 1620, acting through her clique of male supporters. The Mughal Empire's golden age was the reign of Jahangir's son, Shah Jahan (1592–1666), under whom such monuments of world architecture as the Taj Mahal and the Great Mosque at Delhi were constructed.

Decline

Shah Jahan's successor, his son Aurangzeb (1618–1707), was an Islamic puritan and orthodox by temperament; his reign marked the beginning of the end of the Mughal Empire. His relentless campaign in the Deccan (in central India) and wars against Rajputs, Sikhs, Marathas, and Jats drained the royal treasury. Crises in the bureaucracy, weak successors, provincial governors' assertion of independence, and the invasion of the Persian king Nader Shah (1688–1747) in 1739 all contributed to the erosion of the empire. The absence of central authority resulted in the rise of provincial kingdoms, in whose political affairs European traders began to take an active interest. The

British East India Company began to strengthen its military position, and ultimately the whole of India came under the British rule.

Accomplishments

A centralized administration beneath an all-powerful emperor provided stability to the Mughal Empire.

Land revenue was the main source of income, and elaborate arrangements were made for collection and assessment. Many of the administrative features of Akbar's administration, such as division of the empire into provinces, districts, and villages, were retained by the British when they took power.

Urban centers such as Delhi, Agra, Lahore, Dhaka, Surat, and Masulipatnam flourished under the

Mughals as a result of trade and the rise of new markets. The Mughal aristocracy took active part in trade and shipbuilding activities, and the mercantile community accumulated wealth and prospered. India's trade relationships with the outside world expanded; Indian textiles, indigo, and saltpeter were in great demand, while for its part the empire imported bullion and spices. Indian Muslims settled in Southeast Asia, which helped encourage trade with that region. Although Asian merchants initially controlled a major share of oceanic trade, gradually from the eighteenth century onwards European shipping dominated the scene.

Indo-Islamic architecture reached its apogee under the Mughals. The palaces, tombs, forts, mosques and gardens reflected the aesthetic sense, opulence, and settled condition of the great Mughals. The monuments constructed by Akbar were magnificent structures of red sandstone, with pillars along many sides and both carved and painted designs. Under Shah Jahan Mughal architecture made use of marble inlay, foliated arches, mosaic work of precious stones, and copious ornamentation. The Taj Mahal stands apart in architectural splendor and is one of the most beautiful tombs in the world. Landscape architecture, especially gardens, also flourished under the Mughals. Keeping in tune with the

liberal religious outlook of Akbar, manuscripts of Hindu classical texts such as the *Mahabharata* and *Ramayana* were illustrated. Portrait paintings and scenes of hunting, battle, and court life reached their pinnacle under Jahangir. In the arena of music, the musician Tansen (1520–1589) is remembered; his ragas are still popular.

Although Persian was the court language, regional languages developed. Urdu was very popular. The lyrical stanzas of the famous Hindi poets Tulsidas (1543–1623) and Surdas (1483–1563) are recited in northern India even today. The historian Abul Fazal (1551–1602) created the magnum opus *Akbar nama*, an important source material for the reign of Akbar. The vibrant intellectual life of the great Mughals was reflected in the huge imperial library, where records of religious debates that took place at the time of Akbar were preserved. Conflict between liberalism and orthodoxy permeated the Sufi movements also. The concept of the unity of beings, as advocated by Akbar and some Sufi saints, was challenged by strict adherents to traditional Muslim law. Sufi saints such as Ahmad Sirhindi (1564–1624) and Abdul Kadir (1459–1533) endeavored to purge Sufism of liberal practices.

The Mughals had left an indelible mark on the history of the Indian subcontinent. The composite

culture that had started under the Delhi sultanate took a firm shape, and a national culture for the whole of India continued with the Mughal fusion of old with new.

Muhammad

(c. 570–632 CE)

PROPHET AND FOUNDER OF ISLAM

Muhammad is the founder of the religion of Islam. Born into the Quraysh clan in the city of Mecca, he belonged to a family of merchants. At the age of forty he had a vision that turned him to preaching the word of one true God, Allah. He fled from Mecca to Medina where he attracted many Muslim converts. His teachings are recorded in the Qur'an.

Muhammad (570–632 CE) was the Prophet of Islam, now the second largest religion in the world with a following of 1.5 billion people across different regions and races. He belonged to the Arab-celebrated tribe of Quraysh in the oasis town of Mecca, Saudi Arabia. His father died prior to his birth, so he was raised first by his grandfather, Abdul Mutalib, and then following his death by an uncle, Abu Talib. In his early youth, Muhammad adopted his family profession of business in which he prospered more by his personal morals than by the maneuvers of a merchant. He is known to have accompanied his uncle on trading trips to Syria, where he came into contact with Christians and Jews. His community bestowed upon him the honorific titles of *al-Ameen* (the trustworthy) and *al-Sadiq* (the truthful).

Muhammad later made the same journey in the service of a wealthy widow named Khadijah. Despite a fifteen-year disparity in their age, they were married not long after the trip and eventually had two sons and four daughters. It proved to be a long and successful marriage of twenty-six years, broken only by Khadijah's death. One of Muhammad's daughters, Fatimah, married his cousin, Ali, giving rise to the direct line of descendants from the Prophet. At the age of forty, Muhammad claimed that God (Allah

in Arabic) had selected him as a prophet to call his people and the rest of humanity to the worship of this one true God who had also sent the prophets Abraham, Moses, and Christ with the same duty. Muhammad took upon himself the mission of reforming the Meccan society and religion. Messages that God revealed to Muhammad are contained in the Qur'an, the holy book of Islam.

Muhammad gained a few converts to his new religion, Islam ("submission [to God]"). But the powerful, rich Meccan elites, whose socioeconomic interests and political power he challenged, persecuted his followers. These elites were just about to kill him, too, when he moved to another oasis town, Medina (al-Medina in Arabic, "the City [of the Prophet]"). This important event, which came to be known as the Hijra (emigration) in the history of Islam, took place in 622 CE and marks the year 1 in the Islamic lunar calendar.

Muhammad worked to reconcile the warring tribes of Medina into peace and brotherhood. After gaining many more new converts (Muslims), he established the Ummah, a small community of people based solely on faith rather than on tribal, racial, or any socioeconomic relations. Along with preaching God's revelations in the Qur'an, Muhammad instructed his people through his own precepts and practices, called the hadith. The Qur'an and the hadith are two primary sources of Islamic sacred law (sharia). The law calls upon people to establish peace, socioeconomic justice, political enfranchisement, and respect for the human rights of women and minorities. The main thrust of the Qur'an and the hadith is to build an Islamic society on the basis of good conduct, brotherhood, kindness, sharing and caring, respect

Jabal al-Noor, or Mountain of Light, is the place where Muhammad used to pray and meditate.

for others, helping the poor, protecting the helpless, justice and equity for all, promoting virtue, and preventing evil. Muslims take Muhammad as a model of moral perfection.

Under Muhammad's guidance, the small Muslim community (Ummah) that he founded in 622 turned Medina into a city-state. Muhammad framed a signed contract between the Muslims and the Jews of Medina, the Charter of Medina, which is the first of its kind in world history. The Charter guaranteed protection of life and property and freedom of religion to the people of Medina and their allies in the region. The signatories of the charter promised to defend the city-state, to maintain peace and law and order, to submit to equity and justice in judicial and debt matters, to fulfill their obligations in protecting the defenseless, to stop mischief, murder and tyranny, to treat each other as equal partners in peace, and to guarantee religious freedom to all.

The peace and safety of the city-state of Medina under its charter and guidance of Muhammad attracted non-Muslims inside and outside its borders, and the

number of Muslim converts increased. But Muhammad's old enemies in Mecca soon started intrigues with internal and external enemies of the new city-state that threatened Mecca's economic and political domination in Arabia. Skirmishes between the Muslims of Medina and the pagans of Mecca turned into the Battle of Badr in 624. Muhammad with a small band of 313 Muslim followers was outnumbered and outmatched by the 1,000-strong, well-equipped army of Mecca. But the superb war strategy of Muhammad and the courage of his followers defeated the Meccan army. Despite the guarantees in the charter, claims were made following each battle that Jews had sided with the enemies of Medina, resulting in expulsions from the city.

Muhammad said that he initiated his first war of defense (jihad, "making efforts [in the cause of Allah]") with the divine permission that God revealed to him (Qur'an XXII: 39–40). The permission God gave him was to fight against wrongfulness and oppression—not to grab the natural or national resources of an enemy. In his first jihad, Muhammad established

The ink of the scholar is more sacred than the blood of the martyr. • **Muhammad** (c. 570–632 CE)

rules of engagement. He prohibited the killing of women and children and of weak, peaceful, and innocent men. He prohibited the mutilation of dead enemy soldiers and the scorched-earth destruction of an enemy's water and food supplies. He forbade the mistreatment of prisoners of war. Poor prisoners could pay for their ransom by teaching Muslim children reading and writing, and by promising not to fight again. The Meccan pagans imposed two more ferocious battles upon the Muslims, but they failed to obliterate the city-state of Medina.

In 628, Muhammad offered the Treaty of al-Hudaybiya, which guaranteed mutual peace, security, and freedom, to his allies and to his bitter but defeated Meccan enemies. But Meccans soon started violating the treaty, and in 630 Muhammad marched on Mecca with a force of ten thousand Muslims to protect his allies. Before his march, he guaranteed peace and respect to all noncombatants. Mecca fell to his troops without a fight, but rather than slaughtering his enemies, he forgave and embraced them and let them keep their properties. The phenomenal peace of Muhammad turned enemies into friends and Muslims.

In his last Sermon of the Mount, shortly before his death in 632, Muhammad reemphasized the

importance of kindness, of protecting the rights of women and slaves, of the strict prohibition of bloodshed, injustice, and usury, and of the significance of peace and brotherhood. Muhammad reminded his audience, "There is no superiority of Arabs over non-Arabs, and vice versa, nor is there any superiority of whites over blacks, and vice versa."

Museums

A museum is a place for housing, conserving, restoring, and displaying objects and collections of artistic, scientific, or historical significance. These collections are generally selected, arranged, and presented by a curator and made available for public viewing through exhibitions. The museum is an institution with an important role for conserving cultural heritage and in educating the public about the items in its care.

The museum, or institute of the Muses (the goddesses of song, poetry, and the arts and sciences more generally), has been with us for millennia, since the time of the ancients. Plato's library in Athens is thought of as one of the first, while the Musaeum at Alexandria, including the great Library of Alexandria, is considered one of the most famous. Today museums take all shapes and sizes; some are housed in magnificent monuments to preservation, while others are virtual and only accessible online. Museums contain and display all manner of objects and artifacts, from the ancient to the near new, from the conventional to the bizarre. Often thought of as dedicated to archeological, anthropological, and natural history preservations, museums are also dedicated to various themes, places, and peoples: from maritime to space, from science to fashion, from wars to sports, and from Goethe to Elvis.

From "Curiosities" to "Ethnographica"

Starting in the second half of the nineteenth century, anthropological museums began to flourish in virtually all major European and American cities. Through the 1920s these institutions became major centers

for the construction of global narratives, whose rise and fall can be charted over the course of this period. Such an investigation also reveals that museums and global narratives are by no means exclusively Western phenomena.

In the Western world, museums developed out of an impetus to understand and categorize the world. It was during the Renaissance that a combination of mercantile wealth and human inquisitiveness created the first "curiosity cabinets" in Italy. Initial curators of such cabinets had few organizing principles, and they listed the relics of saints along with "curios" of animal and plant remains. Frequently such cabinets presented little more than mementos retrieved from long-distance voyages undertaken in the 1500s and 1600s. Yet already within these cabinets a clear separation between *artificialia* (or human-made artifacts) and *naturalia* (or natural objects) soon appeared. This distinction became more pronounced with the development of the natural sciences in the 1700s. The most significant development was the publication of the *Systema Naturae* (1735) by the Swedish naturalist Carolus Linnaeus (1707–1778). Linnaeus's system classified plants by reproductive apparatus and created a taxonomy that accommodated new plant types encountered during exploratory voyages. While Linnaean categories functioned well in the realm of *naturalia*, one could not extend them to indigenous artifacts. Over the next century, however, scholars invested considerable time and effort in replicating Linnaeus's system for the realm of human artifacts. Their endeavors became even more pronounced as Westerners increasingly encountered non-European peoples following 1750. Expeditions into the African continent or the watery expanse of the Pacific

Ocean returned thousands of objects that stimulated not only curiosity about indigenous peoples but also attempts to classify the world's diversity into well-ordered epistemological systems.

By the 1800s, this search for organizing principles received additional currency from the field of archaeology. Conceived to support the available Greco-Roman literature, archaeology provided additional findings that extended and reinterpreted the humanist traditions. While classical archaeologists operated within the framework of an existing body of Greek and Roman literature, anthropologists were free to conceive histories from the material cultures of so-called nonliterate societies of Africa and Oceania. At the same time, however, there emerged a growing

concern about the availability of indigenous artifacts. Early anthropologists argued that Western expansion brought about the transformation of indigenous cultures around the world. They believed that Western commerce, diseases, and theology reshaped indigenous societies to such an extent that material culture became tainted with Western influence or, in the worst case, ceased to exist. Either way, there emerged a need for an “anthropology of salvage,” which ultimately called for storage houses for indigenous artifacts and established their value as historical sources. This salvage anthropology became instrumental in the creation and sustenance of anthropological museums, which were thus conceived as a thesaurus of human cultures.

The Rise of World History in Anthropological Museums

Armed with new perspectives on the importance of indigenous artifacts, anthropological museums flourished throughout the second half of the nineteenth century. Skilled anthropologists employed the salvage agenda to mobilize civic pride in their respective cities in an attempt to create leading anthropological institutions. Concern over disappearing non-Western heritages enlisted patrons and established networks of collectors. Over the next decades, there also emerged increasing pressure to impose a coherent, orderly framework on the artifacts amassed that could be displayed in the museums' hallways. The concern about vanishing indigenous peoples was nowhere more pronounced than in the United States, whose westward expansion to the Pacific Ocean often conflicted with the interests of Native Americans. The emerging Smithsonian Institution, created by the U.S. Congress in the 1840s, provided a museological example for other institutions to follow in dealing with indigenous artifacts. Within the United States, a number of other anthropological museums emerged, and the competitive atmosphere with regard to indigenous artifacts soon spread to such countries as Germany, Great Britain, and, later, France.

The Fall of World History in Anthropological Museums

A number of important factors contributed to the decline of world historical narratives within anthropological museums. Most telling were novel methodological approaches in anthropology. By the first decade of the twentieth century, museum practitioners began to venture into the wider world. While formerly relying on collectors such as colonial officials, missionaries, and traders, museum anthropologists decried the paucity of indigenous information accompanying the artifacts they obtained. To remedy such omissions, museum anthropologists organized expeditions to particular regions of the world. While the primary objective of such expeditions was still the

collection and study of indigenous artifacts, many expedition participants, dissatisfied with the superficiality of previous data collection, argued for a more localized understanding of cultures, something that could be accomplished only by long-term residence among the members of a particular society. Such considerations, however, could not be easily accommodated in museum displays.

Anthropology's turn from global to local or regional methodology was under way before the outbreak of World War I. This conflict, however, greatly facilitated matters. It disrupted supply lines of collectors around the world, realigned colonial territories, and decimated the scholarly community. Similarly, certain practitioners were stranded as foreign nationals and by default restructured their studies around specific locations. The most prominent example was Bronislaw Malinowski, who as a national of the Austro-Hungarian Empire, ran into complications in the Australian colony of Papua. His ensuing research among the Trobriand Islanders resulted in a number of influential monographs. Although Malinowski did not invent the anthropological method of participant observation, his work enshrined anthropology's turn away from material culture. Museums continued to exist, but theoretical innovation shifted to the university setting. Anthropology's attempts at universal histories gave way to more localized studies that have dominated the discipline ever since.

Non-Western Museums and Their Global Narratives

By 1930, global historical narratives had departed from the hallways of anthropological museums. These institutions still served as important training and employment stations for generations of anthropologists, but novel theoretical constructs emerged elsewhere. Hence emerged the stereotype of anthropological museums as relics of a bygone era so popular in postmodern and postcolonial literature. There exists, however, an interesting byproduct of historical investigations into anthropological museums. Legitimate questions emerged about whether or not

European explorers and colonists in the early 1600s often brought indigenous peoples of the Americas to European cities, treating them as museum pieces, or objects of curiosity. In the 1800s museums became storage houses for indigenous artifacts and established the value of such objects as historical sources.

anthropological museums were indeed Western institutions. While it is difficult to generalize in this context, there seems to be ample evidence that similar processes existed in other societies. Just as Western societies appropriated indigenous material culture to construct historical narratives, so an indigenous appropriation of Western artifacts was a frequent occurrence. Material culture is once again indicative in this case. During the height of the collecting frenzy (three decades before World War I) a number of suspect artifacts started to arrive in anthropological museums. These were things that incorporated Western materials and colors, and whose production involved iron tools. Museum curators generally instructed collectors to abstain from such “tainted” artifacts, yet their numbers started to increase by the 1900s. Deemed inauthentic at the turn of the century, these artifacts are currently restudied to reveal indigenous counternarratives (or, as some historians put it, counterethnographies) to museum world histories. There are even some accounts of indigenous museums, one of the most famous, perhaps, located on the island of Tahiti in the Pacific Ocean. There, inside a *marae* (religious structure) located at Tarahoi, Captain William Bligh (of *Bounty* fame) discovered

an odd collection of artifacts that included mementos hailing from the *Bounty* mutineers—British symbols of power—and a portrait of James Cook. The last was usually carried to arriving ships, whereupon the captains were asked to add their signatures on the back. Bligh did not make much of Tarahoi, but historians now recognize here the emergence of a museum narrating the encounters between Tahitian and foreign societies.

Controversies

A significant issue for any museum is the means by which its artifacts or displays are acquired: were they acquired legally and ethically, or is there some dispute over their acquisition? A series of relatively recent cases have served to bring these issues to the fore. Perhaps the most famous case is that of the Elgin or Parthenon Marbles, a series of classical Greek marble sculptures that have been housed in the British Museum in London since the early nineteenth century, but which are very much wanted by many to be returned to their original home in the Acropolis of Athens. Even today the theft and trafficking of antiquities is an increasingly common

and serious transnational crime. It gained significant international attention following the pillaging and looting of the Iraqi National Museum in the wake of the United States' invasion and war in 2003. In recent years a number of prominent American art museums, including the Cleveland Museum of Art, Metropolitan Museum of Art in New York, the J. Paul Getty Museum in Los Angeles, the Museum of Fine Arts in Boston, and the Princeton University Art Museum have all returned works of art to Italy that were found to be stolen or looted by third parties and sold on. Similarly, the bones of Australian Aborigines acquired on voyages in the early nineteenth century and long held by National Museums Scotland, the Royal College of Surgeons in London, and the National Museum of Ethnology in Leiden, the Netherlands, have recently been returned to their tribal descendants for reburial. While there have been some successes in winning the return of artifacts, particularly human remains, the very nature of many museums and the means by which their numerous artifacts were collected means that this contentious issue will likely remain unresolved as long as there are museums.

Music—Overview

Throughout history music has served as a means of telling (and remembering) stories, as a force in shaping or influencing society, as a mode of spiritual or religious expression, and in political contexts to either suppress or excite people subjected to restricted freedoms. The commercial music industry since the 1990s has fostered the spread of cultural and ethnic identities, especially through the genre of world music.

In examining music's role in history it can be argued that music serves two major roles: it reflects the ideals and realities of societies, embodying history and memory, and it influences and sometimes creates those societal ideals, realities, and possibilities for the future.

Music Tells Stories

Music serves a fundamental role in the history of humanity as a means of telling stories about the past, and thus carrying collective memories into the future. Among the Mande of West Africa, the *jali* are a class of hereditary professional musicians and verbal artists who serve as orators, genealogists, and purveyors of oral history. The power to manipulate words has historically given the *jali* a privileged position in Mande society. Similar to these West African bards were minstrels (secular musicians) in the European Middle Ages (and *jongleurs* before them), who served as storytellers and purveyors of narrative.

Mexico also has singing-poetry traditions, such as the *corrido*—a narrative ballad genre that was especially popular during the Mexican Revolution—in which singers compose verses commemorating past

and current events. Recently a subgenre known as *narco-corridos* has chronicled the exploits of Mexican drug traffickers, frequently celebrating them. On the other side of the globe, programmatic music abounds in Chinese traditional music, such as the *pipa* (lute) composition, “The Great Ambuscade,” which recounts a historic battle between two warlords in 202 BCE. Whether documenting the past or commenting on contemporary events, music helps people comprehend their histories and present realities.

Music and Morality in Early History

Music may provide a means of recording and remembering events, but it can often play an active role in shaping society, a fact that has concerned some of history's most influential thinkers. In ancient China and Greece, respectively, Confucius (551–479 BCE) and Plato (428–347 BCE) developed similar ideas about music's influence on the moral fabric of society. Both believed that the health of the state depended on playing the right kind of music. For Confucius, aesthetic ideals should follow morality: “good” music was that which contributed to good values; the “wrong” music could have severe consequences. A famous story depicts Confucius as advisor to a certain prince of the state of Lu. Against the advice of Confucius, the prince indulged his court with music for entertainment, distracting him from his princely duties and spoiling the economic prosperity of Lu.

Similarly, Plato warned of the danger music posed to society. In his *Republic*, he outlined an ideal society that would ban the music of certain instruments, and he favored the Dorian modal scale as encouraging

If a composer could say what he had to say in words he would not bother trying to say it in music. • **Gustav Mahler (1860–1911)**

Linus teaches Iphikles how to play the lute. Reproduction drawn from an Attic red-figure skyphos (vase) by the Pistoxenos painter (c. 470 BCE). From *Histoire de l'art dans l'antiquité*. Paris: Hachette, 1882–1914.)

bravery. (The Greeks developed seven modal scales based on the unequal intervals between the eight notes in a scale, each mode named for a different city whose mood most closely reflected the scale's tone.) According to Plato, music and athletics could mold the ideal citizen if the training in neither took precedence over the other, but rather complemented one another to provide balance of mind and body. For Plato, as for Confucius, aesthetics were in the service of morality, and indeed he argued that it was more important for a poet to be a good person than a good musician. The conservative philosophies of Confucius and Plato were born of concern about the perceived downfall of their respective societies, and both thinkers believed that changes in the musical cultures of their times were indicative of, as well as causes of, social decline.

Music and Spirituality

Religious worship around the world frequently involves music, sometimes as ornamental to worship services, and other times as the very vehicle for

praising and communicating with a higher power. Yoruba religions in West Africa, Cuba, Brazil, and Trinidad begin services with music as a means of praising the *orishas* (gods) and welcoming them into houses of worship; these traditions also use music and dance as vehicles for inducing altered states of consciousness in which one of the *orishas* may inhabit the body of a believer for a brief time. In Sufism, a mystical branch of Islam, music is used in the *sema* ceremony in order for participants to achieve an ecstatic state so that they may communicate with god. Biblical references to music include the use of music in worship, and the Christian Church was the main patron of Western classical music up through the eighteenth century.

Connections between music and spirituality are often made explicit in legends, myths, and parables, and this other-worldly derivation suggests the importance of music for social groups. The ancient Greeks, for their part, believed that music came directly from the gods, a tempestuous gift from Apollo in Pandora's box. A legend in Indonesian oral history tells of an event around 300 BCE, when a great king won

This series of drawings shows a variety of percussive musical instruments used over time and across cultures: (1, 2) gourd rattles (Hopi of Arizona); (3) rawhide bag with pebbles (Sioux); (4) Rattle of plaited fiber with pebbles (South America); (5) carved rattle in shape of a fish hawk (Tlingit of Alaska); (6) rattle of cocoons of moths with handle (California); (7) shell rattle strung on wooden hoop (California); (8) tortoise shell rattle with leather thong clappers (Arizona); (9) rattle with wrought-iron disk and bells (Africa); (10) cloth belt rattle with deer hoofs and beads (California); (11) ankle rattle with bells (India); (12) musical bones (United States); (13) clappers (China); (14) sheep bone rattle (Spain); (15) hollowed hardwood clapper (China); (16) war drum (Fiji); (17) skin tambourine (Native America); (18) kettle drum (India); (19) two-headed drum (Japan); (20) gong (China); (21) cymbal (China).

a battle in which he gained control of the enemy's bronze drums, thus harnessing the power of the god of thunder as well as presaging the creation of Indonesia's classical percussion tradition, gamelan. More recently, there is a famous Indian folk ballad of Kenaram, a notorious sixteenth century murderer who changed his ways only after hearing the song of a devout poet named Bangshi Das; afterward he became Bangshi's pupil. This Indian ballad articulates the Hindu belief that music is devotion; through music one can attain the highest connection with god.

Other groups advocate the separation of music and spirituality. Despite the exception of Sufism, in most Muslim religious services music is forbidden. In Europe, the influence of Enlightenment philosophy in the eighteenth century encouraged secularization in the arts, and Western classical musicians began relying less on Church patronage. By the end of the century, Wolfgang Amadeus Mozart (1756–1791) was able to work essentially as a free agent in Vienna, and students of Western classical music hold his music in high regard due to his individual genius, rather than any connections between his music and spirituality.

Music's Role in Colonialism and its Aftermath

In the era of European colonial expansion, beginning around the sixteenth century, many groups of people,

along with their music, were subjected to European economic, political, and cultural dominance. Music has been integral to colonial and postcolonial processes. For Europeans, music was occasionally used as tool for the subjection of foreign peoples, and it was often used for religious conversion. For societies seeking to escape from European hegemony, music served a crucial role, particularly in nationalist and independence movements in India, Africa, the Caribbean, and Latin America.

A major consequence of European colonialism was the idea, apparently widely held among both colonizer and colonized, of European music's superiority. There is little doubt that the notion of European cultural superiority greatly facilitated European hegemony, and in this sense music was an aid to colonization. In the late eighteenth and early nineteenth centuries, for instance, Spain sent music teachers along with missionaries to California in order to teach European polyphonic choral singing to Amerindians in the region. In addition to teaching and proselytizing, these emissaries of the crown often forbade the performance of indigenous musical practices.

Strategies for opposing European colonial power often included the reclamation of local musical practices. In India, for example, British colonialism had hastened the decline of court patronage of Hindustani and Karnatak classical music traditions. The rise of nationalism, which culminated in independence in

1948, however, included a renewed interest in and public patronage of traditional arts, and the period saw a rise in education and public performance of Indian music. In Trinidad, steel-band music played a most active role in the independence movement. Along with the leadership of Eric Williams (1911–1981) and the People's National Movement (PNM), Trinidad achieved independence in 1962. In his political campaign, Williams appointed steel-band musicians as his personal assistants, arranged for steel-band performances at PNM political rallies, and, in general, advocated for the steel-band as a symbol of Afro-Trinidadian national culture, ultimately cementing the notion of the steel drum as the national instrument of Trinidad. Similarly, cultural nationalist movements in Brazil and Cuba both countered legacies of Eurocentrism by focusing on the cultural contributions of their African-descended populations.

Composers trained in Western classical music were important in nationalist movements, notably Heitor Villa-Lobos (1887–1959) in Brazil. Such composers were influenced by European works from the late nineteenth and early twentieth centuries, such as Igor Stravinsky's ballet, *Rite of Spring*, which included Russian folk tunes, depicted pagan folk scenes, and caused a riot at its 1913 debut in Paris.

The Commercial Music Industry

From the mid-nineteenth century on, the world of music has been increasingly impacted by the rise of

the commercial popular music industry, especially as it has developed in the United States, beginning in the 1840s with blackface minstrelsy. As it has progressed into the twenty-first century with global pop music, commercial popular music has been created in the context of electronic mass media, the increasing connectedness of previously isolated groups of people due to communication and travel opportunities, and the growth of multinational corporations. While some argue that popular music has served the role of simply advancing the capitalist project (see Adorno 1944), it can also be argued that popular music's position in society is more complicated, as it is often used strategically by individuals and social groups as a means of identity formation and resistance to the alienation of capitalism.

As commercial popular music from the United States has been marketed abroad, musical cultures from outside the United States have in large part been faced with decisions about whether or not to incorporate this music into their own practice. Oftentimes, the decision has been to integrate aspects of Western popular music with the sounds and symbols of local musical practices, thus creating hybrids which are simultaneously international and local. In the 1980s and 1990s in Zimbabwe, for instance, popular musicians such as Thomas Mapfumo created music that was based on rock music instrumentation—drum kit, electric guitars, and keyboards—but which also included aspects of local Shona culture, such as the Shona language and an electrified version of the traditional thumb-piano, *mbira* (Turino 2000).

The ancient Chinese musical instrument called the *bianzhong* (this example from the first century CE), comprises bronze bells of various sizes that are struck with a gong.

Mapfumo was, himself, a pioneer performer in the world music industry.

“World music” emerged as a genre label in the 1990s, a creation of record-company executives as a marketing tool for recordings that mainly included folk and popular styles from countries other than the United States, although occasionally folk music from within the United States itself has also fallen under the world music rubric. In some ways, world music is just another example of the commercial market exploiting cultural difference for economic profit. On the other hand, individuals and their communities now have greater potential access to remote social groups; that exposure has the consequence of loosening the bonds of identification with certain organizations, such as the nation-state, in exchange for others, such as a diaspora group.

Music, Identity, and Visions of the Future

In the late twentieth and early twenty-first centuries, individuals and social groups have often used music as a strategy to form a collective identity. Beginning in the 1980s, children of South Asian immigrants in Great Britain began mixing traditional Indian music with European and North American electronic music, creating a number of hybrids, of which the

most well-known is perhaps *bhangra*. Such hybrids have great significance for young South Asians, allowing them to feel connected, across the diaspora, both to their homeland in India as well as to contemporary Western youth culture. Meanwhile, the U.S.-based country music genre often articulates working-class attitudes, family values, and ethics of hard work. After the onset in 2008 of the international economic crisis, which hit automakers—and their blue-collar employees—particularly hard, the country singer John Rich released the populist anthem “Shuttin’ Detroit Down,” which lambastes corporate greed and government bailouts. Such songs give voice to the twenty-first century North American “everyman.”

If music reflects society, and allows individuals the chance to create society, then it also surely offers glimpses of how people imagine the world should be. In that sense, it has been argued that music is a “prophecy” of the future (Attali 1985). Whatever the case, music’s roles in world history are multiple and significant, meaning that we should all be sure to keep listening.

Music and Political Protest

Because music engages hearts, bodies, and minds it has been a powerful force to foster feelings of solidarity throughout history—in political revolutions, religious reformations, union organization, civil rights movements, and antiwar demonstrations. From “classic” protests songs (“L’Internationale”), to surprising examples of the genre (“Yankee Doodle Dandy”), to newer forms like Thomas Mapfumo’s African-roots-music-inspired Chimurenga, music has brought people together in many calls to action.

Music has been an integral part of expressive culture worldwide and a source of personal and public enjoyment and edification for millennia. Most cultures have used music, and still do, to accompany and enhance every conceivable collective activity and ceremony, from the mundane to the sublime: eating, working, storytelling, worshipping, marrying, performing, mourning, healing, criticizing, satirizing, and just plain celebrating. Because it is an integral part of everyday life and is a medium that evocatively and holistically engages minds and bodies, thoughts, emotions, and desires, it is no surprise that the power of music has been employed to create feelings of solidarity and loyalty to political causes and movements in the modern world.

Songs of Revolution

In the 1950s, the sociologist R. Serge Denisoff wrote that modern protest songs had their roots in the rousing defiant songs of early Protestantism such as “A Mighty Fortress Is Our God” (c. 1528), considered the battle hymn of the Reformation. A century later

Protestant songs rallied radical forces in the English Civil War (1641–1651), notably “Levellers and Diggers” (1649) written by Gerrard Winstanley. As the leader of the radical group True Levellers (1649–1651)—later known as Diggers to further distinguish themselves from a group close in values called Levellers—Winstanley (1609–1676) composed this protest ballad so that the Diggers’ vision and practice of fostering Christian agrarian and egalitarian communist communities could reach the masses in a popular and traditional art form. As social levelers Diggers wanted to “level all estates” (that is, abolish private property rights) and allow all people to cultivate the earth as “a common treasury.” Common ownership, they believed, would ensure universal freedom and the end of privilege; it would bring an end to unequal social, economic, and political power.

Naturally, the Diggers’ seizure and cultivation of common land alarmed local landowners who regarded such acts as threats to their own holdings and to their supply of landless laborers. Consequently, England’s Council of State sent soldiers to break up the Digger communities that spontaneously arose in many parts of the country. Winstanley printed and distributed the song hoping to rally the spirits of Diggers throughout England who suffered persecution by local landowners and clergymen. They learned and sang it in their communities: “You noble Diggers all, stand up now . . . Your houses they pull down, stand up now . . . But the gentry must come down, and the poor shall wear the crown . . . With spades and hoes and plows stand up now . . . That we should now begin, our freedom for to win . . .”

The Levellers, quite similarly, believed in popular sovereignty (government created by, and subject to, the

will of the people) and representative government; equality before the law; and freedom from arbitrary arrest, religious oppression, and taxation without consent. They found resonance in British North America and gave rise to protest movements there in the eighteenth century. A New York grand jury found an early North American protest song, “Come On, Brave Boys” (1734), inflammatory and seditious, and ordered the song sheet to be publicly burned although no author or publisher could be identified. Among the protest songs that articulated colonial discontent and stirred seditious activities before the American Revolution (1775–1783) were “American Taxation” (1765), “The Liberty Song” (1768), “The Taxed Tea” (1773), and “Liberty’s Call” (1775). Rebellious colonists appropriated a bright ditty called “Yankee Doodle” (c. 1755–1775), originally written by a British surgeon to poke fun at rustic American colonial soldiers, and rewrote the words so that its upbeat melody would inspire their troops and serve as a protest against British arrogance. The colonists sang this song at Lexington and Concord to insult the retreating British soldiers, and it became wildly popular among American troops. Songs were spread by newspapers, periodicals, ballad sheets, and broadsides, and by singing in public houses and military encampments.

With the help of these early print media and face-to-face communications, music sustained insurrectionary impulses in France as well. The French Revolution (1789–1799) generated nearly three thousand popular songs, including a huge hit in 1790 “Ça Ira” (“It’ll Be Okay” or “There is Hope”), which people sang in the streets of Paris, Lyon, and Marseilles. Inspired lyricists altered the words as the revolutionary cause became more radical (“aristocrats to the lampposts, we’ll hang them . . .”). During the dark days of foreign invasion, “La Marseillaise,” composed in April 1792 by Claude-Joseph Rouget de Lisle as a simple marching song, sustained revolutionary initiative. French revolutionary forces sang it as a morale booster on the way to Paris to battle the Prussian and Austrian armies that had invaded France to restore the old monarchical regime. Originally entitled “Chant de

The Industrial Workers of the World put their songbook together “to fan the flames of discontent.”

guerre de l’armée du Rhin” (War Song of the Army of the Rhine), it became so popular with volunteer units from Marseilles that it was renamed in their honor. Supporters of the revolution all over France learned the tune and lyrics, and it became the French national anthem in 1795. Although the song has seven verses, today only the first verse and chorus are usually sung. The fourth verse is typical of the song’s defiant, martial, and rousing tone. Even in the twenty-first century, “La Marseillaise” embodies the passion, sense of purpose, and commitment that aroused millions of French people to overthrow their monarchy and fight for liberty, equality, and fraternity.

Singing lifted people’s spirits, made revolutionary ideas and sentiments accessible to the illiterate majority, promoted solidarity across social groups, and invited the dispossessed classes of France to proclaim over and over again their devotion to the Revolution. “La Carmagnole,” both a song and a dance, took its name from the short jacket worn by militant *sans-culottes* (the term, meaning “without knee breeches,” applied to the working-classes). When first sung in August 1792, the song insulted the queen, Marie Antoinette, and anyone who opposed the Revolution.

The French revolutionary tradition provided fertile ground for “L’Internationale” (The International), a song that would become the anthem of the nineteenth- and twentieth-century revolutionary proletariat. Inspired by the establishment and subsequent destruction of the radically democratic and egalitarian

Paris Commune of 1871, Eugène Pottier wrote the lyrics shortly after the demise of the Commune; the French factory worker Pierre Degeyter added a melody in 1888. The song became an international hit as the Industrial Revolution spread across Europe, the United States, and the world. Embraced by socialists, communists, anarchists, and trade unionists, and sung at every one of their meetings and demonstrations, captured well the grassroots, militant, democratic, and anti-capitalist spirit of the early socialist and communist movements. Between 1890 and 1945, “L’Internationale” rivaled “Amazing Grace” and “Silent Night” in international popularity.

Since “L’Internationale” was sung on every continent and in scores of languages, there are various versions of its lyrics adapted to meet the needs of working people in different lands. Translated into Russian in 1902, it was sung at socialist (Menshevik and Bolshevik) and organized workers’ meetings before 1917 and became a crucial expression of commitment to the egalitarian, collective, and emancipatory ideals of the October (Bolshevik) Revolution (1917), and of the world socialist movement during the Russian Civil War (1917–1921). The English version, recorded in the United States in 1935, included references to the Russian Revolution.

An ocean away, *corridos*, folk ballads popular in Mexico from the 1880s to the 1930s, nurtured a sense of popular independence and defiance during the Mexican Revolution (1910–1920). They typically recounted the deeds of individuals whose conduct served as a model to the community. *Corridos* about the revolutionary folk heroes Pancho Villa and Emiliano Zapata conveyed stirring messages of nationalism, class anger, resistance, and hope; not only did such songs ridicule upper-class rule and *gringo* intervention, they recruited peasant fighters for the armies of Villa and Zapata. *Corridos* about Pancho Villa generally described particular battles or his valor, leadership, defiance, and courage. *Corridos* about Zapata were similarly praiseful but more closely tied to land reform and his commitment to end the exploitation of peasants. The theme of defiant and armed resistance to authority conveyed by

such *corridos* had great appeal to a peasantry that enjoyed little economic and political freedom or mobility. Singers (*corridistas*) played in town squares on market days and sold broadsides of new or popular *corridos*. Mexicans who could not read often purchased the broadsides as mementos of the occasion and, hoping to revive the allure of the song as it had been performed, made the broadsides available to literate members of the community. As a folk art form, however, *corridos* were extremely malleable and spread from town to town during the revolution; most were memorized, not written down, so the content changed as it was remembered differently or altered to reflect local sensibilities.

As early as the 1920s leaders of the Communist movement in China believed music could win converts to the Communist cause. Chinese recognition that music had the power to sway people’s outlook and emotions in fundamental ways went back at least twenty-five hundred years to the time of Confucius. Leaders like Mao Zedong (1893–1976), who had peasant origins, understood that song enabled the illiterate peasant majority to express and comprehend everyday needs and realities. Consequently, Communists held that music was the most appropriate and effective medium to teach their revolutionary perspective. They rewrote lyrics that had long accompanied traditional folk melodies and made them into songs of revolution. “Nanniwan” (1943), based on a tune from northern Shaanxi, was such a song. A new genre of Communist revolutionary music during the Chinese Civil War (1927–1949) employed a marching, resolute tempo expressing worker and peasant unity; like the reworked folk genre it protested current conditions but remained optimistic about the future and the outcome of the armed struggle against capitalism, imperialism, and feudalism. Red Army troupes often performed the songs to entice enlistments.

This belief in the politically mobilizing power of music continued after the Communist victory in 1949 when the party controlled print, broadcast, and performance media and Cultural Revolution (1966–1976) was on the horizon. A prominent example was “The East Is Red” (c. 1960) a song that served to rally

X-Ray Spex, Rock Against Racism Rally, Victoria Park, Hackney, East London, 30 April 1978. Photo by Andy Wilson, Creative Commons license.

pro-Mao forces in the People's Republic of China. In keeping with the traditions of Chinese Communist political music, a farmer from Shaanxi province reputedly created the song by putting new lyrics to the tune of a local folk song.

Music of Solidarity and Organizing

In order to inculcate values that were opposed to the individualism, competition, and nationalism inherent in mainstream social and cultural institutions, the Socialist and Communist parties before World War II provided social environments for their members with football clubs, marching bands, plays, musicals, gymnastics, picnics, summer camps, schools, and consumer cooperatives. All these organizations and events were aimed at socializing individuals into working-class solidarity, cooperation, and mutual support. Marching bands accompanied all large leftist demonstrations.

German Communists in the 1920s and 1930s used music to energize their recurrent street protests with songs like "Up, Up Let's Fight." Bertolt Brecht wrote the lyrics, appropriating a thirty-year-old tune popular with supporters of the deposed German emperor. Such militant marching songs primed Communists

for frequent high-stakes street battles with police and Nazis. While mischievously grounded in German popular culture, the songs boosted morale and advertised the Communists' determination to press the class struggle wherever they went. Communists disseminated such songs extensively through daily newspapers and new forms of photojournalism, such as the astonishingly successful *Arbeiter-Illustrierte-Zeitung* (*Workers Illustrated News*). They also used phonograph recordings, live musical performances, and radio broadcasts to build and sustain a broadly proletarian antiestablishment movement during the Weimar Republic.

Protest Music in the United States

In the United States the Industrial Workers of the World—the IWW, or Wobblies—strove to organize all workers, skilled and unskilled, into one big worldwide union regardless of trade or specialization; their radical labor organizers, including Joe Hill, wrote songs that carried the union's message to those who had little formal schooling. The IWW, founded in 1905, relied on songs to encourage protest and resistance because organizers learned that when people sang a song and had a little fun, they retained the

The singer Harry Belafonte, pictured here at a Washington D.C. civil rights march in 1963, was a vocal protestor of racial discrimination. National Archives and Records Administration.

message. Like other groups in other countries, Wobblies borrowed the melodies of commonly known tunes and altered the lyrical content. The Wobblies' lyrics spoke to working people's concerns, recruited them for the union, and created a common bond among them. One of their most recognized songs is "Solidarity Forever," which set new words to the inspirational and well-known American Civil War song "Battle Hymn of the Republic." Ralph Chaplin wrote lyrics that stressed unity over individual efforts—including a strong and defiant chorus—and reflected the IWW's struggles to organize unskilled workers against the bosses. Wobbly songs sustained workers during long strikes (Goldfield, Nevada, in 1906; Lawrence, Massachusetts, in 1912; Paterson, New Jersey, in 1913; and the Mesabi Range, Minnesota, in 1916) and in protest marches before and during World War I. Typical of other militant movements with few economic resources, Wobblies spread their songs by means of newspapers, ballad sheets, and songbooks, and by singing in taverns and itinerant work camps.

The tradition of using popular folk music as a recruitment and organizing tool and as a means of protesting conditions for workers continued in the United States in the 1930s. Some songwriters, such as Woody Guthrie and the folk musicians he inspired, helped recruit for the Congress of Industrial Organizations (CIO) labor federation. Guthrie spread a message of populist protest and hope across the country

during the Great Depression by making phonograph recordings and performing live at work camps. As unions gained collective bargaining rights in the late 1940s, however, U. S. labor songs lost their revolutionary edge and leftists were purged from unions. Still, people facing injustice turned to song to express their hopes, frustrations, and alienation and to protest their conditions.

Music sustained the struggles of civil rights protesters in the United States after 1960. Songs used by union organizers to foster solidarity became staples of the civil rights movement's sit-ins and freedom marches; these included "We Shall Not Be Moved," a black spiritual whose lyrics were changed by striking African American textile workers in North Carolina in the 1920s, and "We Shall Overcome," a Baptist hymn originally called "I'll Overcome Some Day" (tobacco-worker organizers altered its lyrics in the 1940s). Both songs expressed faith that the future would be better than the past, that their cause was just, and that patient nonviolence would succeed in the end. Of the many musical styles prevalent in the early 1960s, only folk music—whether it was developed by the Wobblies and Woody Guthrie and shaped by black spirituals and rhythm and blues, or whether it took shape in "freedom songs" performed by Bob Dylan, Joan Baez, Pete Seeger, Odetta, and Harry Belafonte—protested racial discrimination and became central to building support for the civil rights movement across the United States. In fact, the term

Music doesn't lie. If there is something to be changed in this world, then it can only happen through music. • **Jimi Hendrix (1942–1970)**

“protest music” was coined at this time to identify the socially critical folk music of this era.

This socially conscious stance of folk performers informed the views of a new generation of young Americans, and young blues and rock musicians began incorporating socially aware lyrics into their songs. Stylistically, rock and roll had been considered dangerous music in the United States since the 1950s: it was a raucous music of youthful outsiders that combined African American and Anglo American musical styles, and was performed by black and white musicians for racially mixed audiences. As the civil rights movement peaked and the anti-Vietnam War movement began to pick up steam in the mid-1960s, folk and rock music were at hand with new antiestablishment content and style. An entire oppositional counterculture grew among young people in the late 1960s, and antiwar songs like “War,” an energetic protest song in the African-American call-and-response tradition by Edwin Starr, “Fortunate Son” by Creedence Clearwater Revival, “The Unknown Soldier” by the Doors, and “Ohio” by Crosby, Stills, Nash, and Young made the Top 10 in the pop music charts. Jimi Hendrix’s irreverent, psychedelic rendition of “The Star-Spangled Banner” at Woodstock in the summer of 1969 brought 400,000 fans to their feet. These songs and others found wide play on commercial radio and television (and at live converts) aimed at adolescents and young adults. Responding to and helping to create the antiestablishment mood of a large section of youth, the protest songs were commercially successful, sold millions of records, and were easily reproduced and played using tape recorders and, after 1970, cassette tapes. They entertained and helped politicize millions of people, bringing them out into the streets to engage in mass civil disobedience in protest of the Vietnam War, and to rail against the Democratic (and later Republican) administration that conducted it.

New Genres for Protest and Mobilization

In Great Britain rock emerged as a highly politicized genre in the 1970s under the influence of mellow

yet “ragged” Jamaican reggae and defiant, anarchist, staccato, hard-edged punk music. Commercial radio, transistor radios, and cassette tapes made the music very accessible to youths who approved its socially critical edge and stylistic innovation but lived outside Jamaican and punk enclaves in Britain. Style and content merged: the musicians and leftist politicians who formed Rock Against Racism (RAR) focused on mobilizing working-class youth against racist ideology and organizations, in particular the neo-fascist National Front Party (NF), which had been gaining electoral support among white working-class youth. RAR drew on rock’s defiant style to make political statements and to take public attention away from the NF. Drawing on musical styles with multicultural roots, the RAR’s main slogan was “Black and White / Unite We Fight!” The biggest RAR events took place between 1976 and 1978, when bands like the Clash, Steel Pulse, Stiff Little Fingers, and X-Ray Spex played at giant marches and concert performances in London and elsewhere. Well into 1979 RAR also issued a series of instant public responses to local, racially motivated hate crimes and violence. By 1980, the music of protest had served its purpose: the NF was a spent force in British politics.

From the 1960s onward British and American blues and rock, influenced by African musical forms, influenced musical styles in other countries. As old and new imperial powers they had economic and cultural reach worldwide, and they encouraged and often funded the spread of mass communication technologies—such as commercial radio and television, vinyl recordings, inexpensive cassette tapes and tape players, and transistor radios—through foreign-aid subsidies and new multinational media corporations. Once in place these mass communication technologies served to disseminate indigenous protest.

In Argentina, *rock nacional* (national rock) developed as part of a politicized youth counterculture that opposed the military dictatorship of the late 1970s and early 1980s, explicitly criticized the government, and created an oppositional movement that contributed to the restoration of democracy. The progressive and politicized lyrics of *nueva canción* (“new song”), a protest-music movement of the 1960s and 1970s with

close ties to South American socialist parties, gained great popularity throughout Latin America, especially in Andean countries. Fusing traditional folk-music idioms with commercial Anglo American rock styles, its lyrics commented critically on poverty, social inequality, and imperialism and advocated for greater democracy, social empowerment, and human rights. The movement in Chile was suppressed after the 1973 coup and continued its protests underground.

In the early 1990s, a Haitian group, Boukman Eksperyans, wrote and performed Creole songs that drew on voodoo beliefs and merged them with imported funk rock and dance music. (*Boukman* is the name of the enslaved voodoo priest who instigated the 1791 revolt among slaves that led to Toussaint L'Overture's revolt, which finally gained Haiti's independence from France in 1804, and *eksperyans* means "experience" in Creole, so the group's name had political resonance in Haiti.) Their song "Kem Pa Sote" ("You Don't Scare Me") rebuked the corruption and brutality of the military regime that in 1991 had overthrown the elected president, Jean-Bertrand Aristide, and it inspired an insurgent movement among the Haitian people that ended the dictatorship.

The Israeli peace movement has long used music at its large open-air rallies to oppose government policies regarding Palestinian rights and Palestinian sovereignty. During the First Intifada (1987–1993), songs like *Yorim VeBokhim* ("Shoot and Weep"), which was banned from the radio for months on charges of subversive content, protested Israeli government policy in Palestinian-occupied territories. Israeli peace groups and opponents of Israel's barrier in the West Bank transformed Pink Floyd's late-1970s critique of the British school system, *Another Brick in the Wall*, into a song of social protest regarding conditions in Israel/Palestine, rewriting the original lyrics ("We don't need no education / We don't need no thought control") to read: "We don't need no occupation / We don't need no racist wall." For its part, Palestinian political music has protested the Israeli state as a colonial power and expressed the need for Palestinian sovereignty and a homeland. Appropriating the musical form of hip-hop, the Arabic group DAM rapped in Arabic and Hebrew about national

aspirations, national oppression, social and political inequality, and Israeli government brutality.

In the mid-1970s, political protest led to a new musical genre in the African country of Zimbabwe that was partly influenced by Jamaican reggae (called "African roots music" by its fans and performers) and Anglo American rock being broadcast on commercial radio and recorded onto inexpensive and easily distributed cassettes. This new African music, created by Thomas Mapfumo (b. 1945) and other indigenous singer/songwriters, articulated black peoples' experiences under (and their resistance to) the white Rhodesian colonial and settler system. This genre, which became known as Chimurenga (struggle or liberation) music, blended traditional Shona music with Western rock and jazz instruments and a political message full of symbolic meanings, traditional proverbs, and rock's rebelliousness. These innovations transformed Zimbabwean popular music of the 1970s. Black Zimbabweans flocked to the performances of Chimurenga artists, bought their vinyl singles, and listened to recordings on commercial radio before the white government banned this music. After the ban they listened to it on guerilla radio and bootlegged cassettes. They instantly identified with the music and Shona lyrics, and Mapfumo in particular became a household name. The upbeat, energizing music with its socially critical lyrics but easy, swaying rhythms galvanized the African population and encouraged young people to cross the border into Mozambique for training in guerrilla warfare. In the eyes of many Zimbabweans, including the first president of Zimbabwe, it was Chimurenga music that won the liberation war by invoking the wisdom and guardianship of their ancestors and by emphasizing the necessity of all Zimbabweans to live together, suffer together, and struggle together for the good of all. Mapfumo remains a living cultural icon in Zimbabwe today.

Implications and Directions

Because music is such an integral part of people's lives it will continue to shape and influence their perceptions of what is important politically, their personal and social aspirations, and the ways in

which these are expressed. It is one cultural arena in which ideological struggle and political mobilization will continue to take place as music circulates along with other cultural goods and commodities, sometimes in face-to-face communication or via print and broadcast media, but increasingly via new media technologies like MP3 players; iPods and other personal, portable media players; and music- and video-sharing websites and social networking websites (Web 2.0).

Music has promoted a variety of political ideas and protests, with different cultures and groups appropriating and creating music suitable to their goals. In the 1960s and earlier, music was an integral part of what were more or less organized political movements. Where populist political movements declined, as in the United States and much of Europe in the 1980s and 1990s, politicized musicians took the lead in staged commercialized “mega-events” like Live Aid, Farm Aid, and Band Aid. In these concerts, music itself provided the organizing vehicle. It was mass music that mobilized masses of people. The point was not to protest political or social inequality or to foment revolution but to raise money for famine victims in Africa or dispossessed farmers in the American Midwest—and music still called people to action.

Writing in the late 1990s, Ron Ayerman and Andrew Jamison noted that protest music can still conjure a movement and its meaning long after the movement has ceased to be active; protest music can encode and embody forms of collective meaning and memory; and it can foster processes of identity and identification vital to the emergence and continuance of new political protest movements.

Mysticism

Humans can depart from normal states of consciousness in many different ways—by holding their breath, dancing together, taking drugs, or contemplation. What happens differs from case to case, but people often claim such experiences as a direct encounter of God or other supernatural spirits. Most religions made room for such mystic visionaries, and their lives often inspired new departures, especially when organized groups arose to pursue mystic visions together.

Mysticism is a type of religious experience claimed to involve a direct and personal experience of God, or of some eternal, spiritual element in the universe. Most of the major world religions have a significant mystical dimension to their faith. It is sometimes the case, however, that such mystical trends are not regarded as an orthodox feature of the religion. Although mystical experience differs somewhat from religion to religion, there appear to be features in common. Mystics typically subscribe to forms of spiritual discipline involving meditation or the repetition of the name of the divine. Such disciplines may often involve asceticism or withdrawal from the world. Mystics usually aspire to achieve a form of merging with God, or of spiritual salvation. The process of spiritual training undergone by mystics is often supervised by a spiritual adept or teacher. Within a particular religious tradition, the experiences associated with mysticism may be written in spiritual texts or transmitted orally. However, since the mystical experience is essentially individualistic and subjective, there may be difficulties in comparing the experience of one person with that of another.

It seems reasonable to suppose that people have, from very ancient times, attempted to gain a direct relationship with spiritual elements in the world around them. But documented traditions within the major faiths are much more recent. Hinduism has many traditions that may legitimately be described as mystical, most notably the practice of yoga. This mystical philosophy may be dated to the Upanishads of approximately 500–400 BCE and has been practiced in various forms until the present day. Yoga emphasizes the control of breathing as an aid to concentration and meditation. It is often accompanied by a renunciation of the world and by a tendency toward asceticism. The goal of yoga is that one should obtain union with Brahman, the spiritual force of the universe, and hence release from the cycle of rebirth. The use of yoga postures, or asanas, is but one element of yogic mysticism. In more recent times, celebrated practitioners of yoga include Ramakrishna (1836–1886) and Vivekananda (1863–1902).

Sikhism also espouses a form of mysticism whose goal is a direct experience of the divine. The principal approach is that of *nam japan*, or repetition of the name of God. This method, along with a meditation upon the nature of God, was the mystical approach advocated by the founder of Sikhism, Guru Nanak (1469–1539?). In another Indian religion, Jainism, there is an emphasis upon asceticism, and also meditation. Jainism was founded by Vardhamana (Mahavira), who lived from approximately 599–527 BCE. The ultimate goal of Jaina mysticism is *moksha*, or release from the cycle of birth and death.

Buddhism, founded by Siddhartha Gautama (c. 566–c. 486 BCE), subsequently known as the Buddha, is arguably a mystical religion, although it does not

For several hundred years mystics have been drawn to standing stones found throughout northern Europe, such as these in Avesbury, England.

incorporate any form of divine figure. The practice of Buddhism is derived from the enlightenment experience of the Buddha, achieved after a prolonged period of meditation. The express purpose of Buddhism is to enable human beings to eliminate their feelings of suffering, and the practice of meditation is one of the principal methods used to achieve this. The initial aim of meditation is to calm the fluctuations of the mind, and then to gain insight into the nature of existence. In this way the Buddhist comes to understand that the world is impermanent, and that through nonattachment to the world, one can begin to eliminate feelings of suffering. Eventually

the Buddhist aspires to a state of supreme calmness and equanimity known as enlightenment. Buddhism spread from India to Southeast Asian countries such as Thailand and Cambodia, and north to Tibet, China, and Japan. The Buddhist tradition that developed in Japan became known as Zen, and one of its main exponents was Dogen (1200–1253). Zen has had an important influence on Japanese art and poetry, an example being the work of the poet Matsuo (Basho) Munefusa (1644–1694). Buddhism continues to influence Japanese cultural life to this day.

The Daoist tradition in China advocates a tranquil life, and one in which the aspirant seeks to live in tune

Religion is to mysticism what popularization is to science. • **Henri Bergson (1859–1941)**

Headquarters of Theosophical Society at Adyar, India. In 1875 Madame Blavatsky, a Russian mystic and spirit medium, founded the Theosophical Society in New York with her friend, Colonel Olcott. The organization was a boon to the spiritualism movement. Photo by Klaus Klostermaier.

with the natural world. The Daoist attempts to live in harmony with the Dao, or the creative energy that is present throughout the natural world. The *I Ching* is usually regarded as the principal text of Daoism, and was historically attributed to Laozi in approximately the sixth century BCE.

The mystical tradition in Islam is known as Sufism, a term that may be derived from *suf*, the Arabic for wool. This may refer to the tradition of Sufis wearing a cloak of rough wool. This very much reflects the ascetic tendency, which is an element in Sufism much as it is in other mystical traditions. The aim of Sufis is a direct experience of God. Sufis often traditionally

associate themselves with a religious community, led by a sheikh or spiritual leader. Sufism continues to be an active tradition in the present day.

The approach to mysticism within Judaism is known as kabbalah, and it emphasizes a direct understanding of God as being the force behind the entire universe. Judaic mysticism utilizes meditation and contemplation, and encourages the aspirant to develop a sense of love toward humanity.

Within Christianity the history of mysticism is connected to some extent with that of monasticism, which evolved in Egypt during the third and fourth centuries CE. The early monastics led extremely

simple lives, withdrawing from the world and devoting themselves to God. The monastic tradition was placed on an established basis by Saint Benedict (c. 480–547 CE). Noted Christian mystics include Saint John of the Cross (1542–1591), Saint Teresa of Ávila (1515–1582), and Jakob Böhme (1575–1624).

Mystics have generally attempted to seek the most direct spiritual experience of their particular religious tradition. In so doing, they have often been perceived as a threat by the religious orthodoxy. From time to time, mystics have given expression to subjective experience, and while this may have been contrary to established tradition, it has been a reminder of the attempt to seek direct understanding of the divine. To that extent, mysticism is still an important contemporary tradition, particularly for those who seek that form of religious experience.

From a relatively obscure position in the French military, Napoleon quickly rose at the beginning of the nineteenth century to become the ruler of almost all Europe. He is remembered in world history for breaking new ground in promoting equality, religious freedom, education reform, and introducing a new civil code, the Code Napoleon.

Napoleon Bonaparte was born in Ajaccio, Corsica, and graduated from a French military school as an artillery lieutenant. In 1793 he scored his first victory as an officer in the French Revolutionary army, destroying ten British ships in the harbor at Toulon. He was then made brigadier general, at age twenty-four. On 5 October 1795, Napoleon's ultimate triumph of force was foreshadowed when he used artillery to fire upon a Royalist mob—his famous “whiff of grapeshot”—to protect the Revolutionary government in Paris. Now a national hero, he was promoted to commander-in-chief of the French forces in Italy. From this position he would eventually go on to rule almost all of Europe.

Napoleon married Josephine de Beauharnais in 1796 and immediately left to lead the French army in Italy, which was fighting the Austrians. He was soon victorious and formed the Cisalpine Republic out of part of northern Italy.

When an invasion of England proved impossible, in 1798 Napoleon was sent to invade British-controlled Egypt. He was generally successful in his land battles, but Britain's Vice Admiral Horatio Lord Nelson destroyed his fleet in the Battle of the Nile. Nonetheless, the discovery of the Rosetta Stone and

the many scholars, artists, and cartographers who accompanied Napoleon on the expedition laid the foundation for modern Egyptology, one of his enduring academic legacies.

When Napoleon returned to France, he took control of the government in the coup d'état de Brumaire (9–10 November 1799), becoming, at thirty-seven, First Consul of France. Again faced with the Austrians in northern Italy, Napoleon led his army through the Alps and won the Battle of Marengo on 14 June 1800.

Later in 1800, Napoleon oversaw the drafting of his Civil or Napoleonic Code. Perhaps his most important legacy, Napoleon's code organized the thousands of Royalist and Revolutionary decrees, abolishing feudal privileges and establishing equality before the law. The code also established freedom of religion and the separation of church and state. In 1801 he smoothed relations with Rome by signing the Concordat with Pope Pius VII, bringing Catholicism back to France while, over the Pope's objection, maintaining freedom of religion.

The 1802 Peace of Amiens with England allowed Napoleon to concentrate on domestic reforms, including a nationwide infrastructure improvement program and the first moves in Europe toward universal public education.

On 2 December 1804, backed by the Senate and the people, and to thwart efforts by Royalists to assassinate him, Napoleon consolidated his power still further, and was declared Napoleon I, Emperor of the French. However, his imposition of the progressive Napoleonic Code over his successive European conquests, effectively dismantling the centuries-old conservative

European social order, arrayed all the monarchies of Europe against him, and war soon returned.

In 1805, abandoning plans to invade England, Napoleon moved his Grande Armée to central Europe to meet oncoming Russian and Austrian armies. His greatest victory was the Battle of Austerlitz on 2 December 1805—although it was diminished somewhat by Nelson’s earlier destruction of the French fleet off the coast of Spain at Trafalgar. At Austerlitz, Napoleon defeated a larger force by employing masterful military and psychological tactics.

In 1806, Prussia and Russia declared war on France. Napoleon conquered Prussia and signed a treaty temporarily ending hostilities with Russia in 1807. In 1806 he established the Continental System, an economic blockade of England that lasted six years, doing economic damage on both sides but ultimately failing to break the island nation. He put his brother Joseph on the Spanish throne, but Arthur

Wellesley, the future Duke of Wellington, invaded Spain and the French forces eventually withdrew.

When Josephine proved unable to bear children, Napoleon reluctantly divorced her and in 1810 married the Austrian Emperor’s daughter, Marie Louise. They had a son in 1811.

By 1810, England and Russia were the only major powers outside the French Empire. Czar Alexander had quit the Continental System, demanded that France abandon Poland, and was prepared to invade. Napoleon moved first, and in 1812 led his army into Russia. He won at Borodino on 7 September and entered an abandoned Moscow, which was soon engulfed in flames ignited by Russian partisans. Napoleon withdrew, and the campaign cost him 90 percent of his army. In October 1813, a massive coalition of forces defeated Napoleon at Leipzig in what became known as the Battle of Nations, sealing the fate of the first French Empire.

Jacques-Louis David, *Napoleon in His Study* (1812). Oil on canvas. National Gallery of Art, Washington, D.C.

Paris fell to allied forces in May 1814. Napoleon abdicated on 11 April and was exiled as Emperor of Elba, a small island off the coast of Italy. On 1 March the following year he returned to France to reclaim his throne from the Bourbon Restoration of Louis XVIII. He took Paris on 20 March without firing a shot, beginning the period known as the Hundred Days. He wanted only to govern France, but his old enemies soon moved against him, and after initial success he was defeated at Waterloo, in Belgium, on 18 June 1815. Exiled to the tiny British island of Saint Helena in the southern Atlantic Ocean, he dictated his memoirs and died on 5 May 1821, officially of stomach cancer but possibly, as many historians now believe, of poisoning. His remains were returned to Paris in 1840.

Often considered the father of modern Europe, Napoleon's legacy goes far beyond his military genius, and is subject to a wide variety of interpretations.

Although he promoted the ideas of equality, meritocracy, religious freedom and a common system of law throughout his empire, he was an absolute ruler, suppressing many with whom he disagreed. Nonetheless, the Napoleonic Code remains the basis of French law, and it was the primary influence on nineteenth-century civil codes throughout continental Europe and Latin America. Napoleon's sale of the Louisiana Territory to the United States helped lead to that nation's greatness, and he had a profound influence on the rise of European nationalism: his efforts on the Italian peninsula and in the German principalities foreshadowed the unification of both Italy and Germany. Though the restored old regimes remained influential for a time, Napoleon's example of leadership based on merit eventually became the goal of Western nations.

Napoleonic Empire

The Napoleonic Empire (1799–1815) was the largest, most politically uniform state Europe had seen since Roman times, and it laid the foundation for many fundamental institutions of modern Europe.

When Napoleon Bonaparte became First Consul and head of the French state in November 1799, France had already been at war with the great European powers since 1792 and had acquired several adjacent territories as a consequence. Thus, the First French Republic, founded with the overthrow of Louis XVI in August 1792, had already become an empire by 1799. In 1795, France annexed the Austrian Netherlands, present-day Belgium, turning them into French departments governed from Paris under French laws and institutions. In 1797, they did the same with the all the areas of the Holy Roman Empire—now Germany—on the left (western) bank of the Rhine. In 1795, the United Provinces, the modern-day Netherlands, was renamed the Batavian Republic under a puppet government. In 1796, Napoleon created a “satellite republic” in northern and central Italy with himself as its president—the Cisalpine Republic—and its capital at Milan. In 1798, occupying French armies set up the Roman and Parthenopian republics over the Papal States and the mainland parts of the Kingdom of Naples, respectively, in southern Italy, and the Helvetic Republic in present-day Switzerland; the first two lasted only a few months, and were soon overthrown by an internal revolt; the third is still the official name of the Swiss Confederation. Until a series of military reverses in 1799, France effectively controlled most of western Europe.

The Creation of the Inner Empire, 1800–1805

Napoleon’s first task was to recapture these territories from the Austro-Russian coalition and reestablish French hegemony in one form or another. This he did in a series of well-coordinated military campaigns in 1799 and 1800. By 1801, a general peace had been concluded with all the major powers, culminating in the Peace of Amiens with Great Britain in March 1802. Although Britain and France were soon at war again, France did not return to war with the continental powers until 1805, allowing Napoleon time to consolidate his rule in France itself, in northern and central Italy, and in the Low Countries. Simultaneously, Napoleon cultivated the larger states of western and central Germany within the Holy Roman Empire, winning them over from their traditional allegiance to the Hapsburg emperors with promises of territorial growth at the expense of the tiny imperial states and greater control over their states if freed from Hapsburg domination.

By 1805, the Napoleonic Empire is best expressed as a power bloc, a hegemony, over most of western and southern Europe. This hegemony was exercised in three different ways. The left bank of the Rhine, modern Belgium, and northwestern Italy were annexed directly to France; satellite states were recreated in the Netherlands and north central Italy; the rest of western Germany was the preserve of states closely allied to France: Nassau, Baden, Bavaria, and Württemberg chief among them. These territories became deeply imbued with core French institutions, either by their direct imposition or through free but

Ernest Crofts, *The Battle Of Waterloo* (1877).
Oil on canvas. The battle on 18 June 1815
effectively ended the Napoleonic Empire.

conscious imitation. These were principally the Civil Code, which guaranteed open trials and equality before the law, and the centralized state based on prefects—civil servants appointed by the central government—and departments, the units they administered. The satellite states received constitutions modeled directly on that of France, which created a strong executive and a centralized bureaucracy; everywhere, local laws, weights and measures, currency, and administrative structures were replaced by those developed by the French revolutionaries since 1789. This also meant the abolition of the vestiges of feudalism, of provincial and noble privileges, and the confiscation of the properties of the church. To be within the French Empire meant joining a uniform, standardized political system; the old orders were swept away in every area the French took under their definitive control. Taken together, the areas under Napoleonic hegemony before 1805 became an “inner empire,” the true core of Napoleonic power. Here, French public institutions and legal and administrative practices were readily assimilated, at least by the

local elites, and usually endured after Napoleon’s military eclipse and fall in 1814–1815. This was crucial for the future development of Europe, because the embedding of the Civil Code and the centralized state laid the legal and institutional foundations of many western European states.

These reforms were aimed primarily at increasing state power, and that new power was enforced by the creation of the gendarmerie, a paramilitary police force mainly devoted to patrolling the countryside. Particularly after 1805, when large-scale war erupted again in Europe, this new force was used primarily to impose mass conscription and heavy taxation on peasantries for whom central authority had been a mere shadow before Napoleonic rule. Even in the more stable period of peace, 1800–1805, the arrival of the new state came as a traumatic shock. Much of southern and western France remained under virtual martial law in these years; northern and central Italy saw widespread, if localized, peasant revolts; very traditional forms of local justice and government, based on arbitration, were expunged from rural parts of the Rhineland for example. Independently, the German princes met similar opposition within their own borders. Some aspects of Napoleonic rule, such as the religious settlement or the ruthless imposition of conscription, were never really accepted outside France, or over much of the south and west of France itself.

Nevertheless, the propertied classes, which also included much of the peasantry, benefited from the higher levels of law and order brought to the countryside by the gendarmerie, particularly by wiping out banditry. Justice became quicker and cheaper to obtain under the Code than in the past, and was administered by an honest, professional magistracy. The fair and equitable reparation and administration of property taxes was largely achieved by the compilation of accurate land registers (the cadastre), although indirect taxes became very high under Napoleon. The prefects proved able and honest local administrators, all of which left a deep, favorable impression on the elites of western Europe, even among those politically opposed to Napoleon.

In the eyes of empire builders men are not men but instruments.

• **Napoleon Bonaparte (1769–1821)**

Democratic politics, however, formed no part of Napoleonic rule. The western European experience of the new Napoleonic state did not include meaningful representative, parliamentary government. Also, as the core of the Napoleonic Empire took shape, that core was not wholly French. Many non-French areas, particularly the allied German states, the Rhineland, the Low Countries, and northern Italy, absorbed French institutions and proved better sources of taxes, conscripts, and administrators than western or southern France, where resentment of the revolutionary reforms of the 1790s persisted. When the empire expanded through war from 1805 onward, these areas came to form an “inner empire” around the new territories to the east and south.

By 1805, the Napoleonic Empire had emerged as a direct challenge to other European empires in several senses. Its territorial expanse and the material and human resources it controlled made it an obvious military threat and a regional power of the first order, at least in western and central Europe. At a more structural level, its compact territorial nature and, above all, its centralized, uniform administrative system marked it out as very different from the looser, more arbitrational imperial model of the Holy Roman Empire and of the Habsburg monarchy. On one level, Napoleon now chose to imitate his rivals; on another, they chose to imitate him. In December 1804, Napoleon crowned himself “Emperor of the French,” and according to the new constitutional formula, “the French Republic was entrusted to a hereditary dynasty” (quoted from the coronation oath). In line with this, the Italian and Batavian Republics became kingdoms, the former under Napoleon but effectively ruled by his stepson, Eugène de Beauharnais, the latter under his brother, Louis. However, the real changes in the European order came in the years immediately following the creation of the empire. Fearing that the change of title heralded an attempt by Napoleon to become Holy Roman Emperor, the Habsburg emperor, Francis I, dissolved this ancient institution, and henceforth styled himself

Emperor of Austria. In the same spirit of suspicion about Napoleon’s ambitions, Austria soon joined with Britain and Russia in a new coalition against Napoleon. They were crushed by the French in a lightning campaign in 1805, and when Prussia and Russia attempted to fight on, they were defeated in a series of campaigns in 1806–1807 that took French armies into Russia itself.

The “Grand Empire,” 1805–1814

This round of victories altered the shape of the empire and of Europe as a whole in dramatic, unexpected ways. In 1805, Napoleon seized the southern Italian Kingdom of Naples, placing his brother Joseph on the throne in place of the Bourbons. The states of western and southern Germany were linked together in the Confederation of the Rhine, with Napoleon as its “Protector,” thus providing a new kind of political “umbrella” to replace that of the Holy Roman Empire; territory seized from Prussia and Hesse-Cassel in north central Germany became a new Kingdom of Westphalia, under Napoleon’s youngest brother, Jerome. Further east, following the Treaty of Tilsit, with Czar Alexander I, a new state, the Grand Duchy of Warsaw, was created from the Prussian parts of Poland. Napoleon annexed Tuscany and the Papal States, in central Italy, in 1809, and the North Sea coast of Germany, between the Kingdom of Holland and Denmark, in 1811. After 1805, the Napoleonic Empire was no longer a purely West European state system, but a pan-European Empire. Territorially, the Napoleonic Empire reached its height in 1811. Its own departments, ruled directly from Paris, numbered 130, embracing 44 million inhabitants; when the satellite kingdoms and the Confederation of the Rhine are added, the “Napoleonic hegemony” contained over 80 million people. Appearances are deceptive, however. The territories acquired in this second phase of expansion proved less ready to accept the set of laws and administrative institutions that defined the Napoleonic imperium than those regions under its control up to 1804. Feudalism was much more powerful in

northern Germany, southern Italy and, especially, in Poland, than elsewhere in Europe, nor was the principle of religious toleration readily accepted in many of these regions. Thus, the Civil Code was never fully implemented in many of these areas. Although they became important sources of conscripts for the armies and for supplies, these regions came to represent an outer empire, which never properly absorbed the essence of Napoleonic rule, although the Grand Duchy of Warsaw remained politically very loyal to Napoleon, personally, for having restored its independence. Spain was never really under Napoleonic control, and its resistance proved an important springboard for the British to relaunch the war against Napoleon effectively in 1808, several years before Napoleon's military power was smashed in the 1812 campaign against Russia. By 1814, the "Napoleonic adventure" was effectively over.

The empire's administrative and legal uniformity was not mirrored in Napoleon's economic policies. To defeat Britain by economic means, Napoleon imposed a blockade along the imperial coastlines, which proved largely ineffective. His "Continental System" was a series of treaties erecting customs barriers protecting France from all European competition, even within the empire, creating a "one-way common market."

The Napoleonic Legacy

Napoleon's hegemony over Europe was brief; in some regions, it lasted only three years. Nevertheless, his reforms exerted a lasting influence on how the states of western Europe were governed henceforth. Although the Congress of Vienna, which reorganized Europe after Napoleon's fall, reordered the borders of states to a considerable degree, Napoleonic administrative institutions and, above all, the Civil Code reemerged sooner, rather than later, as basis for civil government in what had been the inner empire, and would become the historic core of the modern European Union. Later, the centralized, culturally uniform model established under Napoleon became the guiding principle of French overseas imperialism, starting with Algeria in 1829 and spreading across much of Africa and Indochina in the late nineteenth century. The legacy of the Napoleonic Empire in European and imperial history is less in Napoleon's transient military exploits than in the durability of his civil reforms.

Nationalism—Overview

In its most familiar but basic nineteenth- and twentieth-century form, nationalism is the doctrine that each nation has a right to its own state, and that a state is legitimate only if it represents a nation. Four interrelated features of the modern world were conducive to the emergence of nationalism: politics, economies, dissemination of text-based culture, and racial, religious, and ethnic differences.

Until recently, conventional wisdom held that nationalism arrived on the world stage in western Europe around the end of the eighteenth century. Its birth was sometimes dated more precisely: 20 September 1792, when the French revolutionary troops who turned back the invading Prussian and Austrian coalition forces at Valmy did so with the cry “*Vive la nation!*” Whether or not the victory was the result of nationalist fervor or effective artillery is moot. But there is little doubt that the mass mobilization with which the French Revolution met its enemies, the administrative and cultural centralization begun by the republic and continued under the empire, and the belief in France’s destiny inspired by Napoleon prefigured many of the themes of later nationalism. So too did the response that France’s victories evoked. Resistance to French armies was carried out in the name of the nation, even when—as in the case of the patchwork of states, principalities, and imperial possessions which was to become Germany—no political entity corresponded to that name. Indeed, it was in the German language that the nation received its first explicit philosophical articulation, in the writings of Johann Gottfried von Herder and Johann Gottlieb Fichte. Once it found expression, the rhetoric of nationalism was

taken up with great enthusiasm in the nineteenth and early twentieth centuries. Wars were fought, dynasties overthrown, empires challenged, and borders redrawn in the name of national self-determination.

The conventional wisdom has been subject to criticism on many fronts. Some historians have argued that nationalism had very little presence in the consciousness of ordinary people until well into the nineteenth century and perhaps even later. Eugen Weber (1976) has shown that most French peasants in the late nineteenth century had little sense of being French. John Breuilly (1982) has argued that nationalism was initially a political project designed to further the interests of elites, and only engaged popular sentiment as a result of the administrative and educational policies of the state. If this line of criticism encourages us to think of nationalism as emerging rather later than the end of the eighteenth century, a second line of criticism locates nationalism earlier. Linda Colley’s (1992) account of eighteenth-century Great Britain tracks the development of a sense of British national identity over that period. Colley’s argument is not inconsistent with, and indeed it presupposes the existence of, an English and perhaps even a Scottish sense of national identity before that. Liah Greenfeld (1992) and Anthony W. Marx (2003) trace the emergence of nationalism back to the early sixteenth century, and Adrian Hastings (1997) has presented a strong case for a sense of English nationhood even prior to the Norman Conquest.

It is important to separate different questions here. One concerns the extent to which nationalism was a significant presence in the consciousness of those in whose name nationalist struggles were carried on. Another concerns the use of nationalist rhetoric by

political leaders, intellectuals, and cultural figures. It may be that Breuilly is right about the relatively shallow roots of nationalism, even in the nineteenth century. But it may also be that Greenfeld and Marx are right in that nationalist rhetoric was making its appearance in political and cultural discourse at least four hundred years earlier. In other words, nationalism may have begun its career as an elite phenomenon, and only become a mass possession very much later.

Definitions

In its most familiar nineteenth- and twentieth-century form, nationalism is the doctrine that each nation has a right to its own state, and that a state is legitimate only if it represents a nation. In more recent years, however, some nationalist movements—for example, the Welsh in the United Kingdom, the Kurds in Iraq—have been prepared to settle for something less than full political self-determination. Although these concessions may be born out of necessity, they suggest adopting a more moderate and inclusive conception of nationalism as the claim that a nation has a right to political recognition, perhaps a degree of autonomy within a federal structure, and that a state is legitimate to the extent that it provides that recognition.

But what is the nation? And what is it about the nation that justifies its claim to a privileged political status? There is a limit to the extent that we can provide general answers to these questions. But there are some general characteristics. Nationalism came on the scene with the idea that a group of people is constituted as a political community through a shared cultural identity, and (enough) people believe that this identity should take priority over others. There is an enormous variety in the constituents of this identity, not only between nations but within a nation at different times. Each nation does have its own story to tell, but the plot may change. Every nation does, however, appeal to a common history, a story of triumphs and disasters, of heroism and betrayal, through which the nation has come to be what it is. Every nation thinks of itself as having a homeland, which is described and celebrated in the nation's art, literature, and music,

and which provides the ground in a near literal sense of its national identity. Typically (though not universally), the national culture is based on a common written language, and members of the nation are able to communicate with each other through that language. The culture is also egalitarian: as Benedict Anderson (1991, 20) put it, the nation is “always conceived as a deep, horizontal comradeship.” This is, of course, compatible with considerable inequality of wealth, power, and prestige. The nation is like the God of the great monotheistic religions: all are equal in the eyes of the nation, if in nothing else. However, insofar as the nation is conceived as the basis of legitimate political rule, nationalism is a populist doctrine: sovereignty is located in the people.

The Origins of Nationalism

Nationalism is the doctrine that a community, united by land, history, and language, has a claim to political recognition. The more visible nationalist movements of the nineteenth century—those of Germany, Italy, Greece, Poland, and many others—sought to remake political borders so that they would correspond to the aspirations of the nations they claimed to represent. It is possible, however, to recognize earlier, less strident versions. English borders were, more or less, secure by the sixteenth century; they were extended by the incorporation of Scotland in 1706. (The attempt to include Ireland was much less successful.) A conception of England, involving landscape (“this scepter'd isle”), religion (Protestantism), history, mythology (Edmund Spenser's *The Faerie Queene* was important), a cast of characters (the English yeoman, the squire), a literary tradition, even special modes of warfare (the long bow), had begun to play an important role in public discourse in the sixteenth century. When England and Scotland formed Great Britain it formed an unusual, but not unique, multinational nation (Canada and the old Soviet Union are other examples). While England and Scotland could continue to celebrate their distinct national identities—though a strong case has been made by Hugh Trevor-Roper (in Hobsbawm

Eugène Delacroix, *Liberty Leading the People* (28th July 1830). (1830). Oil on canvas. Allegorical female figures have prominently stood for countries and their causes.

and Ranger 1983), that Scottish national identity was largely formed in the nineteenth century—they did so as parts of a larger nation, Britain. The monarchy, shared political institutions, and a common written language were important unifying factors. So too was Protestantism, and as this became less important in the nineteenth century, it was replaced by a shared imperial mission.

The story so far focuses on England and later Britain. Many scholars (Greenfield 1992, Hastings 1997) have argued that England led the way into nationalism. And even Marx (2003), who places Spain first in the queue, with France and England close competitors, concedes that the nationalist project was more successful in early modern England than elsewhere. However, this leaves open the issue of whether there were even earlier forms of nationalism, perhaps elsewhere than in Europe. Hastings makes the interesting suggestion that Israel as depicted in the Old Testament served as a model for the early nationalist depictions of England. Certainly, the combination of culture, divine election, and political claims made on behalf of the Israelites has much in common with later nationalism. So too do the claims that Thucydides has Pericles make on behalf of Athens in his Funeral Oration after the first year of the Peloponnesian War. So we will

need to look at the possibility of earlier—and perhaps non-European—forms of nationalism shortly.

Why Nationalism?

Whether or not there are premodern examples, there is little doubt that nationalism reached its zenith in the modern world. Why has the modern world been so hospitable to nationalism? There are four interrelated features of the modern world that were conducive to the emergence of nationalism: politics, economics, the dissemination of text-based culture, and religious, racial, and ethnic exclusions.

Politics

Nationalism is, as both Breuilly and Marx emphasize, a political project. This suggests that we need to examine the emergence of nationalism in the context of changes in the nature of state power. The most obvious of these is centralization: the attempts by the early modern state to establish its position as the sole source of power within an increasingly clearly defined territory. Of almost equal importance was the expansion of the role of the state in social life. It acquired a range of administrative, juridical,

*A national debt, if not excessive, will be to us a national blessing . . .
It will be a powerful cement to our union.* • **Alexander Hamilton (1755–1804)**

policing, infrastructural, and increasingly educational responsibilities. If state coercive power was centralized, its administrative power began to make itself felt in almost all aspects of social life.

Economies

The most important economic change was the spread of capitalist market relations. Ultimately this was to lead to industrialization, but that came much too late (in Britain, in the late eighteenth century; in Europe, North America, Japan in the eighteenth, and in other places even later) to explain the emergence of nationalism (as against Gellner 1983). As market relations spread, previously self-sufficient rural communities found themselves dependent on a wider network of production and distribution. The emergence of a labor market encouraged population movement. Transport, both of goods and of people, improved. If the market was always global in its reach, the most intensive development took place within the borders of well-established states, such as England and France. If the market was not a sufficient explanation of nationalism (as some Marxists may have believed), it defined the social space on which national identities were constructed.

Dissemination of Text-Based Culture

Perhaps the single most important development was what Anderson (1991, 37–46) called “print capitalism”—the explosion in the production and dissemination of texts, increasingly in vernacular languages. If religious texts (especially the Bible) were initially most important, other text-based cultural forms (political tracts, scandal sheets, magazines, plays, eventually novels) developed to take advantage of the new opportunities for influence and markets. The spread of literacy made these products available to a large audience. If market relations were eroding the diversity of cultural forms characteristic of peasant life, the development of print-based culture made more encompassing and richer forms of identity available.

Religious, Racial, and Ethnic Exclusions

Many historians of nationalism (e.g., Colley 1992, Marx 2003) emphasize the role of real or imaginary differences in the construction of nationhood. For Colley, the opposition to Catholic and absolutist France was crucial to the construction of British national identity in the eighteenth century. Marx makes a stronger case: for him, an essential component in the formation of national identities was the repudiation of some identifiable other. Early-sixteenth-century Spain selected the Jews, and most nations followed suit. For England, the exclusion of Catholics helped unify the otherwise heterogeneous Protestants. No doubt internal factors, such as those listed above, also played a role. It is plausible, however, to suggest that a contrast with what is “other” is necessary for a unified identity. All too often, the other is conceived of as a threat that must be repudiated. Religious, racial, and ethnic exclusions lurk uncomfortably close to the surface of the most civilized national cultures.

These four features do not provide a full explanation of the rise of nationalism. History is too full of contingencies for this to be possible. But they provided the environment within which the nationalist project became possible and, for many, inevitable.

Premodern Nationalisms?

Once we have a reasonably clear understanding of nationalism it becomes a broadly empirical question whether there were premodern nationalisms. There are, however, reasons to be skeptical. For much of world history, it would not have seemed plausible to accept the idea that the culture political elites shared with those over whom they ruled was the justification for their political rule. This does not mean that there were not latent cultural similarities between ruling elites and their subjects. Both John A. Armstrong (1982) and Anthony D. Smith (1986) have argued that the early nationalisms of western Europe were able to draw on the cultural resources these provided. (Both Armstrong and Smith conceive these similarities on ethnic lines. This is misleading. Religion and other

This U.S. World War I poster advertising government bonds was aimed at citizens and immigrants.
Library of Congress.

cultural features were more important than descent.) But these cultural ties seem to have played relatively little political role and it would be a mistake to think of them as constituting nations in the modern sense. Perhaps something more akin to the nation came into existence when these communities were faced with a common enemy. It may be, for example, that a sense of French national identity emerged during the One Hundred Years War, and—even earlier—that Vietnamese, Burmese, and Korean national identities came into play as a response to the ongoing struggles with China. A different candidate for premodern nationhood were those small communities, such as ancient Israel and the Greek city-states (excluding the slaves), where there was not a large gap between rulers and citizens, and social life involved a number of common activities and rituals (military service, religion). In these cases, shared experience would have forged a common cultural identity. But this is a long way from the vast nation-states of the modern world.

The Spread of Nationalism

Whether or not there were premodern nationalisms, it was at best an intermittent occurrence. In the modern world, it has seemed inescapable. And it is easy to see why. Once the link between culture and state power had been established, political rule acquired a cultural dimension. This was recognized after the Revolutionary and Napoleonic Wars, and the nineteenth century was the period of “official nationalism” (the term is taken from Seton-Watson 1997). States strove to legitimize themselves in cultural terms. Public displays, rituals, and ceremonials were deployed, and even invented, as part of this nation-building exercise. By contrast, old polyglot empires on the Austro-Hungarian or Ottoman models faced increasing difficulties as their states responded to the challenge of the modern world. The relative success of the United Kingdom in forging an overarching national identity shows that these difficulties were not insuperable. As states expanded their territory and increased their presence in everyday life, minority cultures were faced with a choice, either to accommodate to the dominant culture or to resist. The former choice meant assimilation or marginalization; the latter was the path of national resistance, as the minority culture sought a political embodiment. It may be, as Breuilly argued (1982), that nationalism provided the rhetoric in which intellectuals and political leaders voiced their opposition to metropolitan centers of power well before it became a presence in the consciousness of the people in whose name nationalist struggles were fought. But the rhetoric was—and remains—an effective one.

The sources of nationalism are to be found in the enormous structural changes that were taking place in western Europe in the sixteenth to eighteenth centuries. But it was quickly appropriated in the non-Western world. This does not mean that European models were simply translated, though African and Asian leaders and intellectuals were undoubtedly influenced by what they learned from Europe. Perhaps most important was the experience of European imperialism. Borders were drawn according to the exigencies of colonial rule, and resistance to that

rule itself formed the national identities in whose name resistance was carried out. While postcolonial nations were able to draw on local traditions and history, national identities often faced difficulties when the unity gained through struggle was overtaken by other competing loyalties.

Does Nationalism Have a Future?

For the past two or three hundred years, the nation-state has provided the organizing principle within which much economic, political, and cultural activity has taken place. There is some reason to suppose that this is no longer the case. Production, and not merely exchange, increasingly takes place on an international scale. Improvements in transport and, massively, in communication, have placed even ordinary people in contact with people across state borders. The imperative of economic growth has led most states to subordinate some of their power to supranational agencies and global market forces. National cultures have fragmented along lines that bear little relation to political boundaries. As Hobsbawm (1993, 163) remarked, nationalism “is no longer a major vector of historical development.” But we should be very wary of predicting the demise of nationalism. The explanatory story sketched in above leaves a good deal of room for historical contingency. Whatever its origins, nationalism has become a historical force in its own right, not merely as a medium for other projects. Nations have been able to appropriate and create impressive cultural resources. States retain a good deal of residual power and are well aware of the potency of nationalism to support it. Whether or not globalization will eventually deliver prosperity and security, the contemporary reality for many is poverty and uncertainty. In these circumstances, it is not surprising that nationalism continues to attract the allegiance of states, oppositional groups, and—not least—ordinary people.

Nationalism, Ethnic

If nationalism is defined as an ideology that claims statehood and territorial sovereignty in the name of popular identity, ethnic nationalism is the subset thereof that defines popular identity through a myth of common ancestry. Whether this myth has a basis in fact is largely immaterial, as long as a sense of kinship among the population is manifested and maintained through common culture and tradition.

Ethnic nationalism depends on the sense of kinship or shared ancestry among a population. A shared, distinctive language is the most common marker of ethno-nationalist identity, but other cultural attributes such as religion can serve equally well, as illustrated by the rival ethnic nationalisms of Eastern Orthodox Serbs, Bosnian Muslims, and Catholic Croats (all of whom speak what was once known as Serbo-Croatian) and by the division between Unionist Protestants and Irish Nationalist Catholics (who all speak an Irish-inflected English) in Northern Ireland.

Some of the deep sociobiological antecedents of ethnic nationalism can be recognized in the kinship-based cooperation patterns that humans have in common with a variety of other vertebrates. A shared commitment to guarding a particular territory (as a food source, breeding site, and/or shelter from predators) is one of the characteristic manifestations of such group solidarity. Among all known human societies, analogous behavior patterns have been refined, reinforced, and expanded by the deployment of a vast array of symbolic markers and cultural expressions of group identity. Among even the smallest hunter-gatherer communities, shared rituals, customs, and modes of communication have been used both to

reinforce the social significance of kinship ties and to extend feelings of kinship beyond the relatively narrow group of people who unquestionably share a common ancestral lineage. These cultural mechanisms provide for the adoption of outsiders into the sacred circle of kinship and the casting out of those seen as violating social norms.

Ancient Origins

Starting some ten thousand years ago, as the agricultural revolution transformed societies in the Middle East and elsewhere, the size and number of organized communities began to grow exponentially, as did the importance of maintaining long-term control over bounded territories. The difficulty of maintaining social cohesion increased commensurately, for it was in the course of this socioeconomic, demographic, and cultural transformation that the phenomenon Benedict Anderson has described as “imagined communities” (1991) first emerged. That is to say, communities grew beyond the critical threshold of roughly 150 individuals—the maximum size of a social group all of whose members are likely to develop mutual personal bonds of affection and solidarity. Communal identity now had to be cultivated and maintained by means other than face-to-face contact. Moreover, it had to be kept alive in the face of ever-widening socioeconomic inequalities.

The linked institutions of religion and law, reinforced by a generous measure of brutality, were central to the establishment of social and political authority over imagined communities. To the extent that it was divine sanction of political authority that emerged as the dominant legitimizing framework for

Sheet music cover for “Tell Them that You’re Irish,” a ballad by Tony Farrell. The title/refrain was followed by the words “and never mind their frown.”

ancient states, rulers might not have been overly pre-occupied with the ethnic identity of their subjects. But contact and conflict between states and societies brought ethnic commonalities and differences to the forefront of people’s consciousness. Close encounters on caravan routes and battlefields made members of different communities much more conscious of the cultural characteristics that set them apart from one another. By the same token, the conquest and consolidation of territorially and demographically extensive empires forced regimes to confront the significance of sociocultural solidarity and conflict among their subjects for the cohesion of their polities.

In large states like Egypt and the successive Mesopotamian empires, political authority, social hierarchy, and collective solidarity were maintained by religious and legal systems that enshrined the monarch as either a god or a descendant of the gods. The philosophically more subtle Confucian tradition in China extolled the virtuous monarch as enjoying the “mandate of heaven.” Yet while these

theological frameworks of legitimization were suggestive of claims to universal dominion, the ethno-cultural particularisms in which they were rooted became crucial to the political elites in these states the moment their rule was challenged by alien others. The conquest of Egypt by the Semitic Hyksos invaders and the establishment of their rule there as the fifteenth and sixteenth dynasties (1674–1552 BCE) would seem to belie the significance of ethnicity to political legitimacy in that society. Yet their overthrow by their Egyptian vassals in the sixteenth century BCE was portrayed by rebel leaders as a victory for indigenous Egyptians over ethnically alien, and hence illegitimate, overlords. Similar themes were associated millennia later with the overthrow of the Mongols’ Yuan dynasty (1279–1368 CE) by the founders of the native Ming dynasty (1368–1644 CE) in China.

Conversely, the Neo-Assyrian and Neo-Babylonian empires’ conquests of the bulk of the Fertile Crescent over the course of the ninth to sixth centuries BCE forced them to wrestle with the challenge of consolidating and maintaining their political authority over a diverse array of ethnic groups. One of their standard responses to rebellion by vassal states was the wholesale deportation of tens of thousands of indigenous inhabitants to the far corners of the empire, and the repopulation of the vacated lands by ethnically alien settlers. Such aggressive ethno-demographic engineering reflected the imperial regimes’ acute awareness of the potent interconnection among ethnic solidarity, territorial attachment, and aspirations to political independence.

The most well-known objects of ancient ethnic cleansing are the Jews, and it is among the Jews that one of the most clear-cut cases of ethnic nationalism in the ancient world emerged. It may have been during the Babylonian exile (sixth century BCE) that the distinctive Jewish ethno-theological synthesis crystallized, with its concept of a chosen people bound by a covenant with God to observe his commandments and accept the rule of his law in exchange for living as free people within a clearly bounded territory (“from Dan to Beersheba”). This conception of nationhood,

There is a road to freedom. Its milestones are Obedience, Endeavor, Honesty, Order, Cleanliness, Sobriety, Truthfulness, Sacrifice, and love of the Fatherland. • **Adolf Hitler (1889–1945)**

which blended the idea of kinship with the notion of covenant (a synthesis of ethnic and civic elements, as it were), motivated the reestablishment of a self-governing Jewish community in the ancestral homeland and the eventual reemergence of a short-lived autonomous kingdom of Judah in the second and first centuries BCE. As conveyed through the Hebrew Bible, the ancient Jewish paradigm was to play a major role in the shaping of modern European—and hence global—nationalism.

Modern Ethnic Nationalism

The ancient world presents us with a variety of scenarios, ranging from societies in which ethnic self-awareness was weakly developed and played little active political role to those in which it was central to the legitimization of political authority and territorial sovereignty. Wherever economic decline and geopolitical instability undermined the very possibility of creating or maintaining centralized state power (e.g., early medieval Europe), ethnic nationalism could by definition have little or no occasion to manifest itself. Conversely, the rise of the highly centralized modern state, the growth of geographically integrated economies, and the literary standardization of vernacular languages all begged the following questions. What is the basis of legitimate political power? How should the state define itself in relation to the ethnic and cultural identity of the masses? These issues took center stage in parts of Europe and then spread elsewhere in the context of Western imperial expansion. The steady push toward political democratization in the eighteenth, nineteenth, and twentieth centuries reinforced the growing belief that the collective identity of the populace was critical to legitimizing the very existence and authority of the state as well as the delineation of its boundaries.

In countries where strong preexisting states allowed for the further consolidation of centralized political authority, national identity tended to assume a civic form—that is, it was defined largely in terms of a common set of political values and loyalties, alongside shared territorial attachments and historical

memories. Britain and France are the classic models of this variant of nationalism. But even in these cases, national consciousness was closely associated with particular forms of ethno-cultural and linguistic identity that were actively promoted by state authorities in a concerted attempt to assimilate, suppress, or marginalize lingering regionalist traditions (e.g., Scottish highlander society and Irish Gaelic speakers in the United Kingdom, Breton identity and the langue d'oc tradition in France) that were seen as potential obstacles to the unity of the nation-state. In territorially contiguous, multiethnic empires that were late to centralize their administrations (e.g., the Ottoman Empire and the Habsburg monarchy), efforts to strengthen state authority in the eighteenth through twentieth centuries only served to provoke strong autonomist or secessionist backlashes from alienated ethnic groups (e.g., Armenians in the Ottoman Empire, Czechs and Hungarians in the Habsburg lands). In the course of the nineteenth century, Central and Eastern Europe emerged as the locus classicus (to paraphrase Rogers Brubaker) of modern ethnic nationalism.

If imperial regimes served as the incubators of modern ethnic nationalism, it was the sudden collapse of these empires that led to the growing twentieth-century dominance of the ethnic nation-state as a globally standard framework for the exercise of political authority. The end of World War I was the most violent and dramatic of these watersheds, with the Habsburg, Romanov, and Ottoman empires all falling victim to internal disintegration and/or foreign conquest. National self-determination, championed rhetorically by Woodrow Wilson and Vladimir Lenin alike, became the watchword of the new international order. Even British and French overseas imperial expansion now had to be cloaked in the rhetoric of self-determination doctrine, as in the League of Nations mandates that awarded control over much of the formerly Ottoman Middle East to those two powers on the premise that they would be responsible for leading the colonized peoples of these regions toward eventual independence. In the newly sovereign or newly expanded and reconfigured

Theater placard for *Mirele Efros* (The Jewish Queen Lear), perhaps the most widely performed play in the Yiddish canon. Set in early-twentieth-century Grodno, Poland, the play was a catalyst in the formation of ethnic nationalism for Polish émigrés. New York Public Library.

states of Central and Eastern Europe, policies and institutions were shaped by the struggle to fit divergent forms and conceptions of ethnic identity into uni-dimensional packages called nation-states. Processes that had taken centuries to unfold in the paradigmatic cases of Britain and France were expected to take place virtually overnight in countries like Poland, the Baltic states, Czechoslovakia, and Romania, as they would be later in the post-colonial polities of Africa and Asia. In many cases, the large and diverse ethnic minorities that dwelled within the borders of the new states were pressured to assimilate, leave, or quietly accept second-class status on the margins of the new, ethno-national political orders. The turmoil and repression that

ensued came at a heavy price to democratic institutions and political stability.

In the aftermath of the Cold War, the Eastern European nation-states that emerged from post-1945 Soviet domination owed their capacity for democratization and political stability not only to freedom from Communism but also to the brutal legacy of coercive border changes, ethnic cleansing, and genocide—policies (whether internally initiated or externally imposed by German or Soviet occupiers) that had radically diminished the scale of ethno-cultural diversity in many of these countries. Tellingly, it was precisely the most ethnically diverse Eastern European state—Yugoslavia—that failed to manage the transition from Communism to democracy in a peaceful fashion. In the Union of Soviet Socialist Republics, the façade of ethno-federalism had served the Leninist regime as a propagandist tool employed in the maintenance of centralized, one-party rule. The demise of Communism led to the victory by default of ethnic nationalism as the operative legitimizing ideology in the newly independent republics. Ethnic warfare duly broke out between or within former Soviet republics such as Armenia and Azerbaijan, Moldova, and Georgia.

At the beginning of the twenty-first century, ethnic nationalism remains a powerful and often destructive force not only along the borderlands of the former Soviet Union, but throughout much of the world. In some of the Asian and African states whose post-1945 independence was claimed in the name of nationalism (e.g., Sri Lanka, Rwanda), the unifying emotions of the anticolonial struggle and its memory are proving an inadequate foundation for the construction of cohesive national identities capable of transcending deep internal ethno-cultural divisions. It has been observed that the greater the pressure toward global economic and cultural homogenization, the stronger the backlash from groups seeking political sovereignty as a bulwark for the protection of their ethno-cultural heritage or as protection against the repressive policies of dominant ethnicities. While some manifestations of

this tendency can be dismissed as “the narcissism of minor difference” (Ignatieff 1993, 21–22), no society basing its political institutions on the principle of popular sovereignty can ignore the fundamental dilemma of how to define and lend cohesive form to its citizenry’s identity without sowing discord among the ethno-cultural groups constituting its population.

Nation-State

A nation-state is the singular authority that represents the sovereignty of the people of a nation—that is, a group of people with common bonds of culture, history, and language—within clearly demarcated territorial boundaries. The emerging system of nation-states in Europe during the eighteenth and nineteenth centuries was closely associated with imperialism abroad.

The term *nation-state* ought to be distinguished from two closely related terms, *nationalism* and *nation*. The nation can be thought of as a group of people who are said to have collective bonds—produced by one or more cultural phenomena such as race, language, religion, culture, or history—and affiliation with a common territory. Nationalism is the valuation of the national bond over all other ties and is expressed as the identification of the national collective with a present or anticipated nation-state. The nation-state is the singular authority that represents the sovereignty of the people of the nation within clearly demarcated territorial boundaries.

A “primordialist” view of the relationship between these terms posits that the nation, if not nationalism, precedes the nation-state. In this view, the nation-state represents the primordial nation’s ultimate awakening or coming to awareness of its racial or deep cultural bonds in order to fulfill its destiny in a modern future. Nationalists describe the history of the region as an evolution or awakening toward modern national consciousness. Contemporary scholars of nationalism, most of who can be dubbed “constructivists,” do not subscribe to this view, although the extent and understanding of their constructivism varies.

Constructivists argue that the nation is in many ways the product of relatively recent state formation that sought to integrate different groups into a political body (which comes to be called the nation). The constructivists argue that by interpreting the diverse history and loyalties of the region as the evolution of the nation, nationalists seek to legitimate the present nation-state.

To be sure, some societies, such as China or England, have had long processes of state formation that did produce enduring ties and even an awareness of Chineseness or Englishness, but in the absence of modern technologies or need for strong identity creation, such awareness was often temporary, limited to few groups, and rarely overrode other local or religious bonds. Nonetheless, some historians argue that historical conditions are an important factor and no social formation can be arbitrarily constructed into a successful nation.

The Nation-State System

The nation-state is believed to have evolved from the system of states in Europe traceable to the Treaty of Westphalia (1648), which ended the Thirty Years’ War. The treaty came to inaugurate a system in which, by the nineteenth century, each state was defined by territorial boundaries and ruled by one sovereign. But the system of nation-states is more appropriately dated to its explicit articulation by the philosopher Emmerich de Vattel (1714–1767) in the late eighteenth century, which assumed that states respected the territorial integrity of other similarly constituted states. The Westphalian-Vattelian nation-state was distinguishable from other polities (such

A key element of state building is an effective system of communication and transportation. This photo from south central Namibia shows men working on the Aus-to-Luderitz railway line.

as empires or kingdoms), which had several, often competing, sources and levels of authority (such as the church, tribes, or feudal lords) and in which authority extended over people but not necessarily over territory.

Although in theory a nation-state acknowledged the sovereignty and autonomy of other nation-states, the states were engaged in a competition for resources that entailed not only military conquest and colonization, but also annexation or domination of one another's territories. During the eighteenth and nineteenth centuries these states became increasingly involved in creating the conditions for capitalist competition and wealth accumulation within Europe as well as overseas. Through the nineteenth century, they standardized and regulated their economic, judicial, and political systems while competing for colonies in Asia, Africa, the Americas, and the Pacific. Colonization or semicolonization (such as informal domination through the imposition of unequal treaties in East Asia) was frequently justified by the allegation that colonized societies did not possess the laws and institutions of "civilized nation-states" and were thus not qualified to

participate in the system. Their resources and labor were fair game for colonization and were mobilized for capitalist competition. Thus the emerging system of nation-states was closely associated with imperialism abroad.

Within the boundaries of the nation-state in western Europe and North America, the nation became associated with the doctrine of rights for its citizens. The French Revolution of 1789 protected and enforced human and individual rights as national rights. Article III of the Declaration of the Rights of Man states, "The principle of all sovereignty resides essentially in the nation. No body nor individual may exercise any authority which does not proceed directly from the nation (or the laws of that nation)." In the early stages, the majority of the population, including women, minorities, and slaves within the nation, were not granted rights; their rights were won in the nineteenth and twentieth centuries through political and military struggles. But the fact that such struggle for rights became possible at all was due in large part to the changed foundations of the sovereignty of the state. The state no longer derived its

Before I built a wall I'd ask to know / What I was walling in or walling out.

• **Robert Frost (1874–1963)**

sovereignty, particularly after the antimonarchical American and French Revolutions, from religious or dynastic claims, but increasingly from the idea of the “people” of the nation. The notion of the “nation-people” as the bearers of rights served as a spur for self-determination and fueled the spread of national movements in the territories of the Napoleonic, Spanish, Habsburg, Ottoman, and Czarist empires in the nineteenth century.

Even so, most of these movements were relatively elitist affairs, and nationalism as such did not appear until toward the end of the nineteenth century. According to the historian Eric Hobsbawm, nationality was not viewed as a birthright or an ascriptive status during much of the nineteenth century. Patriotism in the eighteenth-century revolutions in America and France was regarded as a largely voluntary affair. To be sure, the territorial nation-state did produce the cultural homogenization that was a condition for nationalism. But ethnicity, language, and other markers of collectivity were not to become the natural basis of claims to sovereignty until the last decades of the century. There may have been earlier, individual cases of ethnicity or other collective markers being used as rallying points to mobilize the people, but they were isolated and usually elitist; nationalism as a near-universal phenomenon emerged only in the later period and became rapidly realized in the aftermath of World War I.

The Nation-State and Nationalism

Several circumstances led to the emergence of mass nationalism in the late nineteenth and early twentieth centuries. Industrialization necessitated mass literacy and interchangeable skills, which the philosopher Ernest Gellner (1925–1995) argued required the state to produce a culturally homogenous population congruent with state boundaries. The political scientist Karl Deutsch (1912–1992) noted the importance of modern mass media for nation-building projects, and the political scientist Benedict Anderson has emphasized the mass marketing of print media in what he calls print capitalism, which

described the imagined community of the nation to the reading public. Nationalism was also linked to the politics of mass mobilization that emerged with the increasing democratization of European politics after 1880. Some of these conditions—such as the mobilization of certain identities or a form of print capitalism—could be found earlier in imperial China and elsewhere. Nonetheless, it was the simultaneous development of all or most of these conditions within an evolving system of competition between states that shaped nationalism at the end of the nineteenth century as the ideology of the nation-state.

The relationship between nationalism and competition between states was catalyzed by the challenge to British global supremacy in the latter part of the nineteenth century. Nationalism became the ideological means among rising competitor states, such as Germany, Japan, the United States, Russia, and Italy, to mobilize the population and resources within the state's territory in order to gain competitive advantage globally. Political and capitalist elites in these newly industrialized societies gradually undermined the classical liberal principles of free trade—enabling and enabled by British hegemony—by adopting policies to secure a state-protected national economy. The two world wars of the twentieth century were significantly driven by emergent nation-states in the competition for global resources.

Equally important was the mobilization of human resources by the nation-state in the name of the nation. Nationalism was deployed to rally the population and resources for imperialist expansion and war. Mass organizations created by the nation-state to mobilize civilian support for war were first developed by Japan, the Soviet Union, and Italy, nations that were not principals in World War I but that observed the insufficiency of civilian support during the war. These government-sponsored mass organizations, such as the Military Reservists Association formed in Japan in 1910, were developed along the model of a conscript army, imbued with nationalism, and were elevated rhetorically to represent the

will of the people. In this way the government would call on the people to transcend immediate and particular interests; it might, for example, ask people to forego personal consumption or it might call into question the legitimacy of striking workers within the nation. Empire became the reward and glory of mass nationalism.

The events that concluded World War I established the normative principle that the world should be divided into nation-states and dealt an important though by no means conclusive blow to imperialism. The Paris Peace Conference of 1919, the Soviet Revolution, the break-up of the Ottoman and Habsburg empires into nation-states, and the establishment of the League of Nations in 1920 reflected a vision of the world in which the boundaries of the state coincided with that of language and nationality. The creators of the league imagined it as a forum for internationalism based upon cooperation among nations—the individual families of mankind. Two other factors following the war have to be noted: the changed balance of power in the world and the advent of a new discourse of anti-imperialism.

The Soviet Union and the United States of America emerged as new powers with little stake in the old international order based upon the European balance of power; indeed, they were opposed to formal imperialism. Both Lenin and Woodrow Wilson were committed to national self-determination; when the Czarist Empire was reconstituted as the Union of the Soviet Socialist Republics, the constituent parts were theoretically autonomous socialist *nationalities*. The anti-imperialist outlook was undergirded ideologically by the discrediting of the “civilizing mission” of the imperialist powers. Horrified by the scale of devastation of World War I, intellectuals both in the West and in the colonial world launched a critique of the Western ideal of civilization, which in the light of the war they felt had forfeited the right to represent the highest goals or ultimate values of humanity. Colonial intellectuals and leaders in places such as China, India, and the Islamic world began to look to their own civilizations’ traditions to sanction their emergent national movements.

The period after World War I witnessed both the expansion of the nation-state system and the growth of nationalism. While it was hoped that bringing more states under the regulatory mechanisms of the system, such as the League of Nations, would solve the problem of wars among nations, the inherent contradictions in the system actually appeared to intensify. On the one hand, more nation-states and even colonies such as India and mandated territories in the Middle East were part of the League of Nations; on the other hand, burgeoning nationalism justified aggression and domination. Older imperialist nations, faced with the growing phenomenon of nationalism, had to find alternatives to formal colonialism in order to control resources and remain globally competitive. Sometimes this meant developing client states and other subordinate political forms instead of colonies. Rising nation-states such as Germany, Italy, and Japan intensified their pursuit of economic and political supremacy, particularly during the Great Depression. The League of Nations turned out to have no teeth and could not enforce compliance upon those who brazenly violated its covenant, such as Italy and Japan. In part, this was because it was dominated by imperialist nation-states who themselves continued to possess colonies and special privileges. The League ultimately failed in its effort to reconcile the reality of imperialism with the idea of national self-determination.

Decolonization and Globalization

World War II brought about the beginning of the end of colonial empires. It also brought about the triumph of the nation-state as the successor state throughout the colonized world. This was not inevitable, because in several colonial empires, such as the French and the Japanese, there had been considerable experimentation with more-equal affiliations between colonies and the imperial metropole country through ideas of imperial citizenship. One of the most important factors ensuring that decolonization

would yield nation-states was the growing role of the United Nations and international organizations, such as the World Bank, the International Monetary Fund, the Global Agreements on Tariffs and Trade, and the International Trade Organization (later World Trade Organization), and World Health Organization, which tended to recognize only nation-states. The enhanced resources, power, and prestige of the new nation-state system ensured that the only legitimate and viable polities in the world would be nation-states, recognized as such by the system. For example, during the 2003 SARS crisis, the state in Taiwan, which has all the prerequisites for being a nation-state except recognition, had considerable problems gaining access to the services of international organizations—precisely because it lacked nation-state status.

Since decolonization, some have argued that the nation-state form has not provided effective protection against domination by superior powers, which are able to use their continued military and financial might and their influence in international organizations to dominate weaker nation-states. The United States and West European powers have been able to limit the capacity of the new, often institutionally fragile nation-states for self-determination. Similarly, the Soviet Union sought to limit the independence of socialist republics in Eastern Europe and of new nation-states dependent upon its military and financial aid. The effort to create a nonaligned movement during the Cold War, which gained momentum during the Bandung conference in Indonesia (1955), was not very successful, although some states were able to play off superpower rivalries to gain some competitive advantages.

Even though the threat of war between the superpowers was ever present during the Cold War, the existence of the socialist bloc and ideology nonetheless reduced the competitive pressures which had driven nations-states to war during the first half of the century. For better or for worse, the new socialist nation-states restricted the role of multinational

companies and full-fledged capitalism within their borders, and their nation-building projects tended to look inwards. With the fall of the Soviet Union in 1991 and the transformation of China into a capitalist society, nation-states have been turning away from the model of protected development and toward competitive capitalism, now called globalization. In the process, nation-states' relative autonomy from international capitalism and ability to exercise control over their boundaries and identity are once again being affected. Whether or not the new order of international institutions will be able to contain the effects of extreme competition and challenges from the interstices of the system remains to be seen.

Native American Religions

The term *religion* suggests that the sacred can be separated from ordinary life. Among Native American peoples the sacred, the appearance of the extraordinary, and the most meaningful values are intertwined with daily concerns. Thus the pursuit of sustenance, and the making of useful objects or political decisions, may be charged with the presence and power of that which moves the cosmos. The term *lifeway* indicates this close connection.

Such a complex topic as understanding historical consciousness in Native American religions begins with two major insights. First, the religions of the over one thousand indigenous societies of the American hemisphere involve concepts and practices that cannot be separated from the spheres of life in those societies termed economic, political, cosmological, and artistic. *Lifeway* is used here to indicate this seamless interweaving of the spiritual and the historical. Second, history can be recorded and transmitted in forms other than writing. There are, for example, the winter counts on bison hides among the North American Plains peoples, *quipu* or knot-tying of narratives among Andean peoples, and the accordion-style screen-fold picture books of pre-conquest Mexico. All of these historical expressions have oral myth-telling at their core.

Diversity of Native American Religions

The term “Native American” suggests homogeneous societies, but the native communities of North, Central, and South America are extremely diverse in

their lifeways. For example, the archaeological record gives evidence of major cultural and civilizational developments in central Mexico associated with the pyramids at Teotihuacán (200–900 CE), Toltec sites (900–1000 CE), and the massive pyramidal structures built by Mayan peoples in Yucatan, Guatemala, and Belize (300–900 CE). Archaeological evidence in South America suggests that interactions of Amazonian cultures are as complex and old as those in the Andean highlands that led to the late Incan Empire. Moreover, while North and Central America were home to over five hundred native languages, South America has over eight hundred indigenous languages.

In the region of the current United States alone, the diversity of cultural-historical developments is ancient and impressive. An indigenous culture named Hopewell (200 BCE–400 CE), based on corn agriculture, piled soil to create burial and effigy mounds in the central Ohio River watershed. A cultural florescence called Mississippian (600–1400 CE) left temple mounds from the Gulf of Mexico up the Mississippi River to the current state of Wisconsin. Similarly, in the Southwest cultures now called Anasazi and Kayenta (400–1300 CE) built remarkable cliff and pueblo dwellings at many sites including Mesa Verde in Colorado, Chaco Canyon and Montezuma in New Mexico, and Keet Seel and Betatikin at the Navajo National Monument in Arizona. Finally, the pottery skills and irrigation canals for agriculture of the T’ohono ancestors sometimes named Mogollon and Hohokam (100–900 CE) are still used. The progeny of these ancestral archaeological cultures migrated into diverse settings, continued ancient visions, and developed distinct religious concerns.

An Iroquois pictograph from the nineteenth century describes a ceremony in which the Iroquois give thanks to the Great Spirit. Beliefs and practices of native lifeways vary in North, Central, and South America.

Religious Differences Among Native Americans

The North American Plains native peoples place a greater emphasis on individual visions and their relationships, in the symbolism of the circle, with the well-being of the community of life. The Northwest coast peoples celebrate a human community's privileges and obligations in a universe of giving subtly imaged as worlds within worlds symbolically imaged as boxes within boxes.

Southwest Puebloan peoples stress processes of nurturing rain and corn-growth in communitarian ethics and ritual cycles that connect with ancestral histories. Southeastern native peoples continue ancient ceremonies of the first corn of the season, the Green Corn, at which they light the new fire of the community as a cosmological act revivifying creation.

Northern sub-Artic and Artic peoples produced elaborate technologies (e.g., seal hunting, snowshoes, toboggan, igloo) developed for survival in that harsh cold climate as well as intense shamanistic healing practices. A variety of terms are used to refer to all of these peoples in an effort to suggest shared

similarities, such as American Indian, First Peoples, and First Nations. The most appropriate terms that honor their differences are those used by the peoples themselves, for example, Anishinabe (Ojibway), Lakota (Sioux), Yup'ik (Eskimo), Muskogee (Creek), and Haudenosaunee (Iroquois).

Lifeway as the Context of Native American History

The term "religion" suggests that the sacred can be separated from ordinary or profane life. But among Native American peoples the sacred, the appearance of the extraordinary, and the most meaningful values of life are inextricably intertwined with the pragmatic concerns of daily existence.

Thus, the ordinary pursuit of sustenance, the making of useful objects, as well as political decision-making may be charged with the presence and power of that which moves the cosmos. The term "lifeway" indicates this close connection of the spiritual awareness of cosmological forces as the key to understanding the meaning of both individual lives and larger societies.

This drawing of an Inuit mask from Alaska depicts a supernatural being said to control the supply of game. The carved seals attached to the mask suggest that the wearer sought to obtain help for a good seal hunt.

From Denial to Ethnography

Early European studies of Native American societies from the late-fifteenth-century encounter period often reported that historical consciousness and religion did not exist among these peoples. This rejection of religion and systematic remembrance of the past among Native American peoples largely derived from the dominance of the Bible in European worldviews as the singular, literate revelation in which all of world history was revealed. Thus, when unknown peoples were encountered they were explained by locating them within the Bible.

Gradually, the significance of the encounters and the striking differences of native peoples caused Europeans to rethink their own identities and to reflect on their own historical past. The European Enlightenment and scientific worldview from the eighteenth century gave rise to ethnographic analyses of the societies and religious activities of distinct native peoples. Influenced by nineteenth- and early-twentieth-century

anthropology, the historical studies of Native American societies from this period often presented a single informant's remembered culture as normative and timeless for that whole society. These idealized perspectives tended to freeze Native American lifeways as unchanging over time.

Ethnohistorical studies have critiqued these static interpretations by simply presenting the changing descriptions of native peoples within written Euro-American historical records themselves. These academic investigations are significant, but they are strikingly different from native modes of historical remembrance. In fact, many researchers manifest an ahistorical bias that does not allow them to understand the deep historical visions embedded in Native American lifeways. Some of these native modes of historicity are consciously articulated while others are more performative and symbolic. Often these native modes of remembering and transmitting the deeper meanings of their cultures resisted the historical impositions of dominant societies.

*We walk in our moccasins upon the Earth / And beneath the sky / As we travel on life's path
of beauty / We will live a good life and reach old age. • Navajo Blessing*

History Among Native American Religions

From Native American perspectives the question “What ways of knowing history are embedded in Native American religions?” generates strikingly different responses. While not exhaustive, the following list includes some considerations for understanding the history of “Native American religions” from the standpoints of native communities and individuals:

1. Native American religions begin and end with living peoples who speak of the origins of the world and themselves as present realities. This historical consciousness is now both oral and literate, but in both instances it is told by native voice and not locked in library texts or museum holdings of mainstream societies.
2. Discussion of rituals, myths, sacred objects, songs, and seminal places and ideas all hold historical insight for native peoples. Unlike academic history that attempts to describe objectively events, religious objects, and narratives, native historical awareness often sees them as persons deserving respectful treatment, even avoidance if one is not qualified to approach or embrace them.
3. Native history typically makes connections that seem atemporal to Western academic perspectives, but that actually link past, present, and future like a “hypertext” in which past or future events stand in immediate relationship with the present with regard to meaning, causality, and consequence. This shape-shifting and multivocal character of native narratives is not simply a matter of style of literature but indicates ways of perceiving the world that are creatively different.
4. Place occupies a central role in native historical consciousness. In native understanding the sensual engagement with place is an act of cultivation that may bring an individual or group to realization of cosmological values embedded in the lifeway. Sacred places provide foundational insight into that

which gives identity to native peoples. This is unlike the passive, objective roles of the environment in Western historical thought, in which the subjective human constructs, manipulates, and imposes meaning on place.

Narratives as Present Realities

Regarding the first point in the list above: the ways in which native peoples present themselves in remembered form are the myths of origin and legends of historical events considered to have happened since humans arrived. The historicity of myths and legends is a major stumbling block for most Western historians. For example, the Tewa anthropologist Alphonse Ortiz, in recounting the San Juan Pueblo origins, gave a strikingly simple and direct account of his people, saying: “In the very beginning we were one people. Then we divided into Summer people and Winter people; in the end we came together again as we are today” (Ortiz 1969, 29). Understanding this complex mythological statement involves research into Tewa language, myth, social structure, political governance, and religious ecology. That is, the myth provides insight into the living social structures of San Juan Pueblo, and the myth provides formative insight into Puebloan understanding of who they are as a people from the origin time into their present homeland.

The Jemez Pueblo historian Joe Sando (1982, 2) observed that:

If we accept Native North American oral history . . . then we can start with the ancient people who have been in North America for many thousands of years and still allow for European and Mediterranean colonists to strengthen or boost the developing culture. This appears to be what indigenous people have been saying in their oral history. But later Europeans with their “proof positive” and “show me” attitudes have prevailed, and remain largely unwilling to consider, much less confirm, native creation accounts.

Sando claims a literalist interpretation for myth based on the living presence of his people in their ancestral Pueblo homes. Acceptance of the historicity

of myths is a major challenge for historians, but it also opens the possibility for “seeing with a native eye” the historical facts embedded in these stories (Capps 1976, 9).

The Oral Native Voice

The second point in the list draws attention to the need for native voice in reconstructing Native American religious history. Deep authenticity and fragility of native voice are found in the oral narratives that transmit the creation stories, legends, and tales of the people. Actual native voice, layering of stories within stories, and the immediacy and intimacy of oral narratives are crucial correctives to a view of native history that abhors subjective interpretation, ambiguity of outcome, and experiential voice as authoritative.

When oral stories are labeled myths it accentuates their sacred, revelatory character, but that term may also situate the stories as timeless, unchanging, and permanently past. When native peoples narrate stories of origins they may or may not be evaluated according to their conformity to traditional versions. Often narrations are accompanied by rituals that emphasize the living, present character of the beings, places, and events named. Thus, among a number of native nations there are animal-addressing, place-naming, ethic-declaining narratives that accompany major rituals. These should not be seen as either simply describing past events or as objectively categorizing land, animals, or laws.

For example, the Midewiwin ceremony of the Anishinabe peoples of the Great Lakes region transmitted narratives of these tribes’ origin-migration. Named geographical locations not only indicate where the ceremony had been performed but they are also honored as significant stopping places of sacred, spirit beings (Manitou). In effect the ceremony of Midewiwin validated the migration and formation of this Great Lakes people by appealing to the ancient spiritual animal masters. Midewiwin has been described as an “extinguished” ceremony in some academic works, but native practitioners have reasserted the contemporary survival and relevance of this ceremonial complex. While not all Anishinabe religiosity can

be collapsed into Midewiwin, the revitalization of this ceremony in the contemporary period accentuates an emphasis in native religious understanding that formative cosmological experiences endure into the present and identify living people as much as ancestors, according to the author Wub-e-ke-niew (1995) in *We Have the Right to Exist*.

Cosmological Narrative and Song

The third point draws attention to the interactions of rituals, myths, sacred objects, songs, and seminal places and ideas as having the status of “persons” in Native American religions. While this complex of relations is differently expressed among particular peoples, one striking example comes from the Gitskan peoples of central British Columbia.

Each Gitskan house is the proud heir and owner of an *adáox*. This is a body of orally transmitted songs and stories that act as the house’s sacred archives and as its living, millennia-long memory of important events of the past. This irreplaceable verbal repository of knowledge consists in part of sacred songs believed to have arisen *literally from the breaths of the ancestors*. Far more than musical representations of history, these songs serve as vital time-traversing vehicles. They can transport members across the immense reaches of space and time into the dim mythic past of Gitskan creation *by the very quality of their music and the emotions they convey...*

Taken together, these sacred possessions—the stories, the crests, the songs—provide a solid foundation for each Gitskan house and for the larger clan of which it is a part. According to living Gitskan elders, each house’s holdings confirm its ancient *title to its territory and the legitimacy of its authority over it*.

In fact, so vital is the relationship between each house and the lands allotted to it for fishing, hunting, and food-gathering that the *daxgyet*, or spirit power, of each house and the land that sustains it are one. (Wa and Delgam 1987, 7, 26)

The historical testimony of this complex of songs and rituals connects architecture and traditional

environmental knowledge. Gitskan elders voice their concerns in these religious performances for the cosmological and historical continuity of community vitality.

The Linkage of Past, Present, and Future

Regarding the fourth point, namely, the simultaneity of memory in Native American religions, the Pawnee/Otoe author Anna Lee Walters (1992, 77) wrote that she:

discovered two principal sequences of tribal history. The first starts at the beginning and works its way toward the present. The second starts with the present and works its way back to the beginning. Although there may be discussions on the history of the people moving to a particular place, for example—isolated events—often these historical notes seem to be just that until they are pinned down in this large framework.

Interpreting these dynamics of native historicity may necessitate abandoning chronological, linear, interpretive-building emphases on personalities, events, or social and economic forces. In the time-linkage narratives of Native American lifeways the primary focus is more typically on seminal realities of place, action, and spiritual presence. Rather than accept ideas or mental constructs as primary, the mutual participation of humans and the beings of the Earth opens a way toward understanding the wisdom of history.

A striking illustration of this complex linkage is the tobacco symbolism found throughout the American hemisphere. In one particularized expression of tobacco ceremonialism the shaman-healers of the Warao peoples of the Orinoco Delta in Venezuela describe the history of human consciousness as beginning in the House of Tobacco Smoke. When a Warao shaman applies tobacco smoke to a patient or a victim, he breathes a cosmological force that simultaneously reaches back to primordial origins, heals in the present, and establishes ethical responsibilities and orientations into the future. For the Warao

wisdom-keepers tobacco symbolism is a linkage to an archaic shamanistic substratum that still extends throughout the American hemisphere, according to Wilbert in *Mystic Endowment* (1993).

Place and Historical Consciousness

Finally, a widespread cultural activity among Native Americans that provides exceptional insight into their historical consciousness is sensing place. Native sensing of place is a daily, lifeway engagement with the local landscape as a means of cultivation of self and community. Ordinary lifeway interactions with local places are charged with stories that transmit ethical teachings, community identities, and cosmological presences.

The felt authority of the past in a particular place is communicated with humor and poignancy by the Western Apache, whose understanding of place is likened to drinking deeply of the ancestral wisdom that resides there. Such wisdom cannot be taught by rote but is awakened by engaging place deeply with all of the senses, with one's body. This is a historical consciousness that acknowledges informative ideas rising up from soil, that filters stories linked to places through one's own emotions, and that searches visually and intellectually for a whole understanding. After hearing a story of an Apache ancestor who fooled Coyote by enticing him to look up at her in a tree, Keith Basso describes how an Apache wisdom teacher, Dudley Patterson, affirmed his deep yearning to know the historical presence in places, saying:

"Our Ancestors did that!" Dudley exclaims with undisguised glee. "We all do that, even the women and children. We all look up to see her with her legs slightly apart. These places are really very good! Now you've drunk from one! Now you can work on your mind."...As vibrantly felt as it is vividly imagined, sense of place asserts itself at varying levels of mental and emotional intensity. Whether it is lived in memory or experienced on the spot, the strength of its impact is commensurate with the richness of its contents, with the range and diversity of symbolic

associations that swim within its reach and move it on its course. (Basso 1996, 143, 145)

Thus, Native American lifeways provide multiple ways of thinking about history, namely, in terms of the precontact history of Native American societies, the history of the encounter with European cultures, and the modes of historical consciousness embedded within Native American religions themselves.

Natural Gas

Natural gas consists primarily of methane. It is often located alongside other fossil fuels. Cleaner than other fossil fuels, gas is an important source of energy, both as a gas and in a liquified state, used in heating, cooking, and powering automobiles. Before it can be used as a fuel, gas must be processed to make it near pure methane.

Natural gas is a flammable mixture of hydrocarbon gases, formed primarily of methane (CH_4) and produced by the anaerobic decay of organic material over the course of millions of years. The history of natural gas usage goes back in time at least three thousand years, to the ancient civilizations of India, Greece, Persia, and China. But extensive use of natural gas only occurred following the 1960s.

At the beginning of the third millennium, natural gas fulfils a vital role in the global supply of energy. As with other important sources of energy, such as oil, the forces of demand and supply dictate that the location of known natural gas reserves brings with it a certain degree of political and economic power. As of 2009, Russia is the both the world's largest producer of natural gas and home to the world's largest proven natural gas reserves. The Middle East—including Iran, Qatar (home to the world's largest natural gas field), Saudi Arabia, and the United Arab Emirates—is also known to have significant proven reserves of natural gas.

When early civilizations first came across natural gas seeping out from under the earth's surface through fissures in rock and in the form of mysterious flames, they believed it to emanate from supernatural powers. Such experiences with natural gas flames were especially common in ancient India, Greece,

Natural gas spurts from an underground well.
New York Public Library.

and Persia. However, around 600 BCE the Chinese learned to use natural gas flames to boil brine, separating out the salt and providing drinkable water. Indeed, Confucius wrote of wells 100 feet deep along the Tibetan border.

In 1785 Britain was the first country to commercialize the use of natural gas, using it to light up houses, streets, and the like. Some four decades later, in 1816, natural gas started to be used for street-lighting in the United States. Natural gas was first discovered in North America as early as 1626, when explorers observed that Native Americans in the area of Lake Erie were igniting gases that seeped out from the earth's surface. The first natural gas well, however, was only dug in the United States in 1821, in Fredonia, New York, by William Hart. On 27 August 1859, Edwin Drake found both natural gas and oil at some sixty-nine feet below earth's surface. Drake's findings marked a new age for natural gas production in North America. Prior to his work, natural gas was primarily produced from coal. In order to commercialize his well's capacity, a pipeline was built from the well to a nearby village, Titusville, Pennsylvania.

Generally speaking, in the nineteenth century it seemed that natural gas was about to gain a vital role in Europe and North America as a lighting fuel for homes and public streets. But its role was limited due to the difficulty in transporting it from the well to its end-users, as the existing pipeline infrastructure was not capable of doing the job. Moreover, with the advent of electric power in the 1880s, natural gas lights were replaced by electric lights.

As natural gas had lost its role as a lighting source, the natural gas industry searched for new uses for its product. In 1885 the inventor Robert Bunsen invented a device that used natural gas for cooking and heating, allowing its flame to be regulated. The Bunsen burner diversified the potential benefits of natural gas and encouraged the global demand for it. However, the difficulty in transporting gas to its potential users continued to restrict its actual usability.

Improvements in pipe-making, metals, and welding technologies during World War II made pipeline construction more economically attractive. Thus, after the war the world began building an extensive network of gas pipelines. Today, this network consists of over 1 million miles in the United States alone (enough to stretch to the moon and back twice). The

location and control of these pipelines, particularly across international borders, is a potential source of political and diplomatic tensions; as occasionally experienced between Russia and some of its former satellites, such as Belarus and Ukraine, during the early 2000s. Moreover, the utilization of natural gas was diversified to include water heating, space heating and cooling, and as a fuel for generating electricity. The transportability of natural gas opened the possibility of using it for a variety of home appliances—for oven ranges and clothes dryers, for example.

The oil shortages of the 1970s turned the world's attention toward ways of conserving energy, while a search for cheaper, more available energy sources also began. The rise of environmental awareness in the 1960s and 1970s further impacted the energy industry, encouraging the development of energy generation sources that would be less polluting. As a result of these developments, natural gas became the preferred fuel for energy generation. But while natural gas is cleaner than other fossil fuels, it nevertheless does contribute to carbon emissions, and given that it consists primarily of methane, natural gas is a greenhouse gas.

Continued oil shortages and concerns about environmental quality are expected to further increase the demand for natural gas. Compressed or liquefied natural gas is considered a cleaner and economically competitive alternative to automobile fuels such as petroleum and diesel. As of 2009 there are approximately 10 million natural gas powered vehicles in use around the world, many of them as public transport such as buses. Changes in the generation segment of the power industry, such as turning to fuel cells, which are combustion-free, and the quest for pollution-free power generators capable of being sited at the end-user's place of consumption, also are expected to increase our reliance on natural gas.

Nature

All cultures depend on the natural world—plants and animals, the weather, the sun and the sea—for their sustenance. Likewise, each culture has creation stories that classify and provide ethical concepts about its place in the natural world. But not all cultures embody the multitude of universal laws, physical matter, and forms of life on Earth as Western culture does, and attempt to express it all as a single concept called *nature*.

The cultural historian Raymond Williams, in his book *Keywords*, traces the changes in usage of the word *nature* in the English language from the thirteenth to the eighteenth century. He concludes that *nature* “is perhaps the most complex word in the language” (Williams 1976, 184).

Scholars who study the history of concepts of nature often point to Asian cultures such as China and Japan to make the distinction between Eastern and Western concepts of nature. In their essay collection, *Asian Perceptions of Nature*, Ole Bruun and Arne Kalland find that no Asian culture has a single term that encapsulates all of nature. Kalland and S. N. Eisenstadt say that among the Japanese, “reality is structured in shifting contexts and even in discrete ontological [relating to existence] entities, as opposed to the absolutist Western approach” (Bruun and Kalland 1995, 11). Likewise, when a researcher asked villagers in Sri Lanka if they had one word “which means things such as forests, wild animals, trees, birds, grass and flowers,” responses varied, including “thick jungle,” “sanctuary,” and “all sentient beings” (Bruun and Kalland 1995, 153).

The literature on the etymology of the word *nature* is complicated. *A Documentary History of Primitivism*, Arthur O. Lovejoy’s study of nature in Greek

and Roman history, outlines the birth of the concept. The word *natura* meant “genesis, birth, origin.” The Greek poet Homer (c. 700 BCE), in providing a physical description of an herb, also provided its character, its “nature.” To the Greek dramatist Aeschylus (524–456 BCE), “nature” referred to visible characteristics that are assumed to be innate. The contrast between reality (nature) and appearance occurred as well. For example, the pre-Socratic philosophers distinguished between the appearance of a couch and the true nature of a couch—the wood from which it is constructed. During this period people also came to think of nature as the entire cosmic system and its laws.

The English writer C. S. Lewis in his *Studies in Words* writes: “A comparatively small number of speculative Greeks invented *Nature*—Nature with a capital.” This invention required “taking all things they knew or believed in—gods, men, animals, plants, minerals, what you will—and impounding them under a single name; in fact, of regarding Everything as a thing, turning this amorphous and heterogeneous collection into an object or pseudo-object” (Lewis 1967, 35, 37). Clarence Glacken, in his *Traces on the Rhodian Shore*, reviews the force of the design argument in the history of nature from its emergence as early as the Greek historian Herodotus (484–425 BCE) through the seventeenth century CE. Conceptions of the “purposefulness in the creation—that it was the result of intelligent, planned, and well-thought-out acts of a creator,” including a sense of the fitness of nature to human needs, have been important in Western constructions of nature (Glacken 1967, 39).

From its beginning then the word *nature* referred to the whole material world and to intrinsic form and creative forces. One meaning of the word

This Maoist Chinese proverb says: man must conquer nature.

nature was enfolded within another. During the fourteenth century *nature* as “the essential quality or character of something” took on the additional sense of “inherent force.” By the seventeenth century *nature* as the material world overlapped with *nature* as intrinsic form and creative forces. Thus, *nature*, which refers to a “multiplicity of things and creatures, may carry an assumption of something common to all of them” (Williams 1976, 185).

People also personify and abstract nature. The ancient Greek philosophers, taking a stance that was common in paganism at the time, believed that the natural world is alive, an all-encompassing animal with both mind and soul, binding animals (including humans) and plants in intellectual, psychic, and physical kinship. Plato (428/7–348/7 BCE) in his *Timaeus* conceived of the soul as female. Lovejoy suggests that the Roman orator Cicero (106–43 BCE) propelled the concept of nature as goddess from the Greeks into the eighteenth century. On the other hand, Carolyn Merchant, in *The Death of Nature*, traces the tradition from the Neoplatonism (Platonism modified in later antiquity to accord with Aristotelian, post-Aristotelian, and Eastern conceptions) of the Roman philosopher Plotinus (204–270 CE) to twelfth-century Christianity, which placed a female nature “as more powerful than humans, but... subordinate to God” (Merchant 1980, 10). Nature personified as female contains a good deal of ambiguity, being seen as chaotic and destructive, as innocent and tainted, and as an expression of the divine order. C. S. Lewis argued that this personification of nature as female has been the most difficult to overcome, but many environmental historians say the seventeenth and eighteenth centuries were the time when nature was most rigidly confined and its long history of vitalism (a doctrine that the functions of an organism are caused

by a vital principle distinct from physicochemical forces) reduced.

Modern Times

Carolyn Merchant locates “the death of nature” in the rise of mechanical philosophy. Such thinking is associated with the philosophers Francis Bacon (1561–1626) in England and René Descartes (1597–1650) in France. These men, critical of organic worldviews in which the world is personified as a forceful, living body, viewed nature as passive, inert matter that is acted upon by physical laws that are set in motion by a clockmaker deity. One result of the Scientific Revolution was that female nature was transformed “from an active teacher and parent... [to] a mindless, submissive body.” That body was submissive first to God and then through God to humankind (Merchant 1980, 190).

Natural historians, strongly influenced by the explanatory power of mathematics and physics, continued to search for stable order in the rapidly increasing numbers of animals and plants that resulted from the voyages of discovery from the fifteenth to the nineteenth century. The Swedish botanist Carolus Linnaeus (1707–1778) created the first universally accepted system for organizing the members of living nature in an arrangement that apparently revealed God’s design. Continuing a Greek tradition, however, Linnaeus viewed change in nature as fundamentally cyclical, always returning to the same starting point.

Mechanical philosophy located nature in mathematically based laws that play out in the physical world, in which the Earth can be understood through “a series of deductions from abstract premises” with little consideration for final causes and less interest in the abundance of life (Glacken 1967, 406). Although Linnaeus participated in the urge to render a nature ordered by abstract laws, he also inspired the rise of natural history by giving naturalists tools to organize their botanical discoveries. The obsession with documenting and organizing the abundance of life derives as well from a group of writers, many of them influenced by Linnaeus, who returned to classical ideas of

Many cultures attempt to control nature through ritual. This drawing shows Tohono O'odham (Papago) in the desert of southern Arizona participating in a rain dance.

organic nature, argued for final causes and design in nature, and sought them in observations of the sensory world. The Englishman John Ray (1627–1705), the leading natural theologian, in his *The Wisdom of God in the Works of Creation* (1691), emphasized the interrelatedness of animals, plants, and habitats as evidence of a wise creator. Naturalists who came later continued to investigate the intricacies of relationships in nature even as they moved away from the argument from design.

One of the most persistent characteristics of nature throughout the sixteenth to eighteenth centuries was the law of subordination. Lovejoy, in his *The Great Chain of Being*, outlines the belief that the deity appointed each species a fixed place in an eternal chain of being from the lowliest maggot through humans to God. The task of natural history was to fit new discoveries into the appropriate link in the chain. The environmental historian Donald Worster, in his *Nature's Economy*, traces the history of nature as both a sacred and an economic system from the Greek word for “house” (*oikos*) through its amplification to refer to household management, the political “oeconomy” of human societies, and nature’s economy. Thus, Linnaeus, in his essay, “The Oeconomy of Nature”

(1749), describes nature as the “earth household” in which God is the “Supreme Economist” who rationally ordered the cosmos and “the housekeeper who kept it functioning productively” (Worster 1985, 37).

By the beginning of the nineteenth century two scientists—the English geologist Charles Lyell (1797–1875) and the German geographer Alexander von Humboldt (1769–1859)—began a discovery process that swept away the singular chain and the stable taxonomy (scientific classification) and led to questions about the role of a designing deity. In their footsteps walked the English naturalist Charles Darwin (1809–1882), who discovered a basic key to understanding the history of nature. Benefiting from Lyell’s understanding of the age of the Earth’s crust and its history of sometimes-violent change and from Humboldt’s discoveries of geographical diversity and mutual dependency in plant groupings, Darwin sailed to the New World, arriving in 1835 at the Galapagos Islands, an isolated archipelago off the coast of Ecuador in South America. The creatures that he saw there were very like and yet very different from South American species. His observations led him to develop the theory that isolation, chance migration, and fit with a specific environment lead to the evolution of new species.

The English economist Thomas Malthus's (1766–1834) *An Essay on the Principle of Population* gave Darwin the mechanism for evolution: the elimination of the weak and the survival of the fit. Darwin called this mechanism “natural selection.” When he published *On the Origin of Species* in 1859, the objectified view of material life of the mechanical philosophers, as well as the eternally fixed singular chain of being of the natural theologians, was challenged by a world that Darwin called “an entangled bank, clothed with many plants of many kinds, with birds singing on the bushes, with various insects flitting about, and with worms crawling through the damp earth.” The result was nature that, although partaking of universal, unchanging physical laws, had a distinctive history: “whilst this planet has gone cycling on according to the fixed law of gravity, from so simple a beginning endless forms most beautiful and most wonderful have been, and are being, evolved” (Darwin 1964, 489–490).

The Age of Ecology

Nature, in gaining history, regained some of the vitality that it had lost under the reign of mechanical philosophy. Darwin took the Linnaean conception of a stable chain of being and put it in motion through competition and co-adaptation. The historian Donald Worster emphasizes the shift during the late nineteenth and early twentieth centuries to an imperfect nature—communities of competing lives that are contingent along axes of space and time. The ecologist Paul Sears situates Darwin's centrality to ecology in his observation that “environment had from the beginning built itself into the very form and organization of all forms of life” (Sears 1950, 56). Scholars generally credit the German zoologist and comparative anatomist Ernst Haeckel (1834–1919) with coining the term *oecologie* (by 1893, *ecology*) in 1866. Worster agrees with Sears that Haeckel grounded the web of life in Darwin's theory that the economy of nature is governed by relationships that derive from the struggle for existence.

The lack of a designer did not imply that no order exists in a nature that is conceived of as ecological. During the early twentieth century botanists and plant geographers in the United States and Europe gradually

discovered in plant communities a changeable, active nature. By the 1930s this nature was defined most forcefully in the work of the U.S. botanist Frederic Clements (1874–1945). He argued that nature is dynamic but that change occurs in patterns of “successional development” over time. Innovation through competition is progressive in the sense that a specific habitat “begins with a primitive, inherently unbalanced plant assemblage and ends with a complex formation in relatively permanent equilibrium with the surrounding conditions” (Worster 1985, 210).

Both ecology and the earlier natural history understated the roles of inorganic forces in the creation and maintenance of life. Under the ecosystem concept that was developed by the British botanist Arthur George Tansley (1871–1955) in 1935, mechanical philosophy returned through twentieth-century thermodynamic physics as a powerful approach to constraining nature. Uniting living and nonliving aspects of the world under the processes of energy flow emphasized nature's processes as historical while repudiating the organic community posited in Clements's version of nature. Nature as ecosystem is as linear as nature as climax community, but time moves toward entropy (gradual decline into disorder) rather than toward progress. As Donald Worster describes it, “the ecosystem of the earth, considered from the perspective of energetics, is a way-station on a river of no return. Energy flows through it and disappears eventually into the vast sea of space; there is no way to get back upstream” (Worster 1985, 303). Both Clements and Tansley, however, assume a predictable trajectory in natural history.

Historical nature by the end of the twentieth century had acquired randomness, chaos, and chance. The ecologist Daniel Botkin's *Discordant Harmonies* posits an organic nature, a “living system, global in scale, produced and in some ways controlled by life” (Botkin 1990, 189), which may be modeled through computer programs, uniting Clements and Tansley, but with a critical twist. Nature abstracted is essentially ambiguous, variable, and complex; time is not singular but rather a sheaf whose arcs and marks are defined by probability, “always in flux, changing over many scales of time and space, changing with individual births and deaths, local disruptions

and recoveries, larger scale responses to climate from one glacial age to another” (Botkin 1990, 62). In the twenty-first century nature has a radically contingent history that is particularly troublesome in light of the role of nature in human history.

Nature and Humans

Exploring the other side of the equation—how to place nature in history—requires considering the place of humans in nature. Glacken’s *Traces on the Rhodian Shore* covers the preindustrial history of humans and nature. He posits that throughout time the West has regarded the natural world with several questions, all arising from the sense that the Earth is an inherently habitable place for humankind. Is this Earth apparently so fitting an environment for organic life, “a purposely made creation”? What is the influence of the Earth’s climates, physical terrain, and continental configuration, that is, the environment in which life is embedded, on the shape of human culture and on individual health and morality? Finally—and coming increasingly into play from the eighteenth century to the present—in what manner have humans through their artifice acted as “geographic agents” changing nature “from its hypothetical pristine condition” (Glacken 1967, vii)?

Much of people’s attempt to describe the history of nature has centered on the first issue—on teleological aspects of nature. Although the idea of nature as a product of design arose independently of the concept of environmental influence, each reinforced the other. Organic life (including humans and their cultures) was seen as adapting to “purposefully created harmonious conditions” (Glacken 1967, vii). Human artifice, distinct from “first” nature and exemplifying the human place in the chain of being just below the Creator, constituted a “second” nature cultivating and adding improvements to the design. From the Greeks until the eighteenth century Western conceptions of nature in human history portrayed it as the world out there to which humans adapt—but part of that adaptation is to order nature. Human creations of second nature, through domesticating animals and hunting, through cultivating crops and digging canals, settled

wild lands. However, until the seventeenth and eighteenth centuries such activity assumed an inviolate stability in first nature.

As nature itself began to develop a contingent history during the modern era, humans began to recognize their role as agents of geographic change. Human history—emerging during the Renaissance out of a growing self-consciousness about the power of human control over nature and pushed by the belief that such power distinguishes humans from the rest of nature—became a narrative about harnessing the elements (through arts such as alchemy, which was a medieval chemical science and speculative philosophy aiming to achieve the transmutation of base metals into gold) and transforming the landscape for aesthetic and economic purposes. Just as the Age of Exploration contributed to an emerging sense of nature’s history, it also offered comparative evidence of the interactions between human history and natural history. In addition to new animals and plants, the discovery and exploration of the New World offered an aspect of nature seemingly untouched by human artifice. Glacken says that by the eighteenth century the French naturalist George Louis Leclerc, Comte de Buffon (1707–1788), relied on the contrasts between Europe and the Americas to construct his history of the Earth as ultimately “seconded” by the history of human striving. Buffon, who little appreciated the wild, uninhabited places on Earth, saw second nature as both an improvement of first nature and an improvement of human civilization.

Agents of Geographic Change

In the New World the importance of modern humans as agents of geographic change was more obvious. Early commentators such as the Swedish botanist Peter Kalm (1716–1779) noted that settlers were replacing old environments with new and raised questions about their impact on first nature and whether second nature improved the prospects for human habitation. Industrialization in the United States and Britain accelerated the transformations of nature, sharpened the distinctions between city, country, and wild places, and dislocated increasing

*The flesh grows weary. And books, I've read them all. / Off, then, to where I glimpse the spray
and squall / Strange birds delighting in their unknown skies! • From "Sea Breeze" by
Stéphane Mallarmé (1842–1898), translated by Richard Wilbur (b. 1921)*

populations from labor on the land to labor inside factories.

Romanticism, a transcontinental philosophy that granted privilege to first nature as an organic force in human history, made the most influential critique of people's attempts to second nature. Where Buffon argued that Earth history is improved by the shift from first nature to second nature, the U.S. Romantic transcendentalist and nature writer Henry David Thoreau (1817–1862) countered that Earth has its own history, which humans destroy by seconding nature. For the Romantics people who embedded themselves in first nature—returning at least to the countryside and at best to more untrammelled spaces—countered what the Romantics viewed as the growing dominance of mechanical philosophy and its attendant materialism and repression of the innate spirit in life.

Another key figure in the effort to place nature in history was a contemporary of Thoreau—the U.S. scholar George Perkins Marsh (1801–1882). Environmental historians widely credit Marsh's *Man and Nature: or, Physical Geography as Modified by Human Action* (1864) as the first comprehensive analysis of the harmful effects of human modifications on nature. Marsh compared soil erosion and forest destruction in Vermont with degraded environments in the Mediterranean basin and histories of land and resource use in Europe and Asia and concluded that "man [sic] is everywhere a disturbing agent. Wherever he plants his foot, the harmonies of nature are turned to discord" (Marsh 1965, 36). Marsh urged his contemporaries to be cautious in seconding nature, always to consider what must be learned from the priorities of first nature.

However, Marsh's image of people as disturbers of a pristine nature raises one of the most controversial meanings of nature for contemporary environmental history. Marsh and Thoreau, like many people of the nineteenth and twentieth centuries, make sharp contrasts between a world of nature "out there" and people. The question of people's place in nature has been answered ambiguously for the past two thousand years. One of the dangerous ambiguities about nature is that it may both contain and exclude people. During the nineteenth century critics of industrialism often

argued, as Marsh and Thoreau do, that the artifices of people had shifted from improvement to destruction and were not seconding but rather were disturbing nature's history. People and their artifices then become unnatural, alien to nature. Similarly, during the early twentieth century two key figures in the age of ecology, Clements and Tansley, disagreed on the role of people in nature, with Clements making a sharp distinction between the disturbance brought by the plow and presettlement prairie biota (the flora and fauna of a region) and Tansley arguing that people can make ecologically sound changes by their artifices.

The U.S. environmentalist Aldo Leopold said that the twentieth century would require an ecology-based "land ethic" that "changes the role of *Homo sapiens* from conqueror of the land-community to plain member and citizen of it. It implies respect for his fellow-members, and also respect for the community as such" (Leopold 1949, 204). Marsh, Clements, and Thoreau shared Leopold's view.

This controversy over the role of nature in human history continues into the twenty-first century. Most fundamental is the question of whether one may speak of a nature as existing free from human modification. Raymond Williams says that "we have mixed our labor with the earth, our forces with its forces too deeply to be able to draw back or separate either out" (Williams 1980, 83). Drawing on Williams, the historian William Cronon suggests that the trouble with wilderness is its erasure of the history of human striving from natural history, and the historian Richard White poses nature in contemporary times as an "organic machine"—a symbiotic meld of natural processes and human artifices (White 1995, ix). But for Williams the second nature that people have created is socially repressive, materialist, and polluted—toxic for humans and the rest of the organic world. The historian J. R. McNeill's *Something New under the Sun* reinforces the troubling reciprocity between recent understanding of the history of nature as not only changeful but also unpredictable and the disruptive forces of human history. McNeill says that during the twentieth century people took a planet whose future was uncertain and made change even

more volatile, primarily through technological and economic imperatives, thus creating a “total system of global society and environment . . . more uncertain, more chaotic than ever” (McNeill 2000, 359). Indeed, the most pressing global issue for the twenty-first century is the environmental future.

Navigation

The knowledge required to sail a ship between two known points by the shortest good way, and in the least possible time, is called navigation. Throughout history this science has been passed from generation to generation of seafarers; it includes the knowledge of prevailing winds, winds caused by seasonal changes, sea and tidal currents, water depths, and the capability to estimate the sailing time between various ports.

The science of navigation, or the charting of a ship through the water from one place to another, can be categorized as coastal, ocean, or practical navigation. Coastal navigation is practiced within sight of land, and orientation is provided by data such as the profile of the coastline, knowledge of conspicuous landmarks, water depth, and local sea currents. When sailing across an ocean or a large stretch of water beyond sight of the coast, a mariner will register his approximate position by dead reckoning. This is the method by which a ship's position is estimated by using the knowledge of the position at departure, the steered courses, and the distances made good since departure. Because a number of uncertain factors influence these calculations, the resulting position is not entirely reliable. The uncertain factors are the speed and direction of sea currents and leeway (the angle between the course steered by the compass and the course made good, and caused by the wind pushing the ship sideways). During a voyage the error caused by these factors cumulates so that the fault in a dead-reckoned position can become considerable, and lead to a dangerous situation. An exact position, a "fix," can be found by observing celestial bodies, a calculation, and a subsequent construction in the sea chart.

Practical navigation, although not the discussed in this article, is called seamanship, and includes the knowledge how to handle a ship, its rigging and sails, and maneuver the vessel.

Navigation in the Ancient World

Navigational methods and techniques were developed independently in several parts of the world. From drawings in pyramids it is known that Egyptian seamen used sounding rods to measure the water depth beneath their vessels. When Persian and Arabian mariners sailed across the Indian Ocean, and, roughly from the eighth century CE, toward China, they used a wind rose for orientation, based on the points of rising and setting of fixed stars. Latitude was estimated by observing the altitude of the sun and the polestar. In the ninth century, in some parts of the Indian Ocean, shore-sighting pigeons were used on Persian ships to set course to the nearest land. Around 650 CE Arabs, who were experienced in finding their way in the desert by observing stars, used a compass rose of which the points were named after the points of rising and setting of fixed stars. The lodestone, with which iron can be magnetized so that it points toward the north, was not used by Arab and Persian navigators before the end of the eleventh century. By the fifteenth century Arab seamen used the *kamal*, an instrument for measuring the altitude of celestial bodies, to estimate their latitude.

Sailors from islands in the South Seas traditionally crossed large stretches of ocean using a "wind compass," with which the directions of islands were defined by the character of the wind (e.g., moist, hard, dry, or gentle). Their "star compass" was defined by

History is a guide to navigation in perilous times. History is who we are and why we are the way we are. • **David C. McCullough (b. 1933)**

the directions in which a number of bright stars were seen. The polestar was used for an indication of latitude and the constellation of the Southern Cross was used to set courses. Pacific islanders memorized “zenith stars” for a number of islands, that is, stars with a declination equal to the latitude of the island in question, and which are known to pass overhead there, from east to west. By observing a star’s position they could see if they were to the north or the south of their destination, and adjust their course accordingly. South Sea navigators observed birds, cloud formations, and ocean swell for orientation and as an indication for their position.

Celestial Navigation

Navigation as we know it today was first practiced by Phoenician and Greek seafarers, beginning after the sixth century BCE. They navigated in the Red Sea and the Mediterranean in much the same way as Arabs, but had the advantage of sailing in an enclosed sea where land is never far off.

The first seaman said to have steered by stars was the mythological Odysseus. At one stage, as he crossed the sea during his imaginary voyage, night after night he had to keep the stars of the Great Bear on his left hand. This was the method of steering by horizon stars. A star was observed shortly after rising (or before setting) and used as a compass direction. After a while the next rising (or setting) star, with more or less the same amplitude, was used to steer by in the same way and thus the ship was held on the same course without the use of a compass. During daytime the position of the sun was observed and used for orientation. Culmination (when the sun reaches its highest daily position in the sky) indicated the south (or north), while in low latitudes sunrise and sunset pointed to two other major compass directions, east and west. In northern latitudes the polestar, although some degrees off the celestial North Pole, observed in combination with the Great Bear, also indicated the north. South of the equator, experienced seafarers could, at least for a while, still use the Great Bear to locate the north. They also estimated their position

with the use of phenomena observed around them, such as the direction and force of prevailing winds. At night zenith stars were indicators for their position relative to the northern and southern shores of the Mediterranean, while the altitude of the polestar and the sun at noon provided an indication of latitude. Knowledge of longitude was based on sailing times between the eastern and western shores of the Mediterranean. The magnetic compass was probably introduced on ships in the Mediterranean by crusaders, during the thirteenth century. Sea charts and sailing directions, still in manuscript, came into use in that area in the fourteenth century and after the art of printing was introduced in Europe a century later, these aids were used more generally.

In the early Middle Ages, Norsemen and Irish monks started to cross the North Atlantic Ocean toward Iceland. Because of the long Arctic summer, stars were of less use to navigation here than in southern latitudes. To estimate the position relative to the track to Iceland, the Shetland Islands and the Faeroes were used as “steppingstones.” These navigators also observed migrating birds, which showed them in what direction land was, and there is mention of Norsemen using ravens taken on board for this purpose. Seamen found that a group of clouds over the horizon indicated still-unseen land. When visible, Norsemen used the polestar for orientation at night, and the sun during daytime. They probably also used these celestial bodies for setting out their courses. The magnetic compass came into use in the north of Europe after it was introduced in the Mediterranean.

Navigation with specially developed scientific instruments, and tables with astronomical ephemeris, dates from the time of the maritime expansion of Portuguese and Spanish navigators, in the fifteenth century. When the Portuguese embarked on their voyages along the west coast of Africa their courses were generally north-south. They found their latitude by observing the polestar at night, and during daytime from the sun’s altitude at noon. For their observations they used the mariner’s astrolabe, a navigating instrument that was developed out of the astronomical astrolabe, probably around 1445. The cross-staff,

This line drawing depicts ships making their way across Lake Tanganyika in colonial Africa.

inspired on the *kamal*, and used for the same purpose, was introduced at sea about 1515. Beyond the equator, which was reached by 1474, the polestar is no longer visible. Although the Southern Cross had been seen by Portuguese seamen already in 1454, it was found that there was no southern polestar. It was then decided to try to improve the method of finding latitude from the sun's altitude at noon. As a result the first day-to-day declination tables of the sun were compiled. When Columbus sailed toward the Americas in 1492, he was provided with such tables in manuscript. Columbus was also the first to observe westerly variation. Variation is the angle between the directions of the magnetic and the geographic North Poles, and depending on the place on the Earth, it can be easterly, westerly, or zero. As the position of the magnetic pole changes slightly over a year, the variation increases or decreases. It is important that, when setting a course, the value of variation is taken into account.

After the first Atlantic Ocean crossing, and the crossing of the Indian Ocean in 1497, east-west courses were sailed more frequently, and it became necessary to measure longitude. The difference in longitude between two places can be expressed in the difference in time between the two. Columbus tried to find his longitude in the New World from observing a lunar eclipse, which he knew would also occur in Spain. He compared the local time of his observation with the predicted time it would occur in Spain. The effort failed because of the inaccurate prediction through imperfect knowledge of the moon's motion.

The Nuremberg astronomer Johann Werner, in 1514, was probably the first to suggest that longitude could be determined by measuring lunar distances, the angle between the moon and a fixed star. The moon moves across the sky relatively rapidly. At a given time the angle between the moon and a particular star is the same for every observer who can

The sextant, an instrument that measures the angle between any two visible objects, made ocean travel safer and quicker.

see them both. The angle between the moon and a number of stars (called the distance) can be calculated ahead for certain dates and times, for a particular (prime) meridian. An observer measuring the angle would compare the result and his local time with the predicted result and time, and the difference between the two times would provide the difference in longitude. Werner's method is feasible, but at the time it was technically impossible to develop sufficiently accurate instruments and lunar tables. Ferdinand Magellan's astrologer in 1519 unsuccessfully tried to find the longitude in South America by conjunction of the moon and Jupiter. Failure was blamed on errors in the predicted astronomical ephemeris.

Navigators sometimes used the variation of the magnetic compass for estimating their longitude. Because of the apparent relation between longitude and variation, sixteenth-century scholars designed methods of converting variation into longitude. For this to be successful in practice, however, the method requires a vast amount of data on the magnetic variation, which was not available until the eighteenth century, when Dutch navigators estimated their longitude with variation during crossings of the Atlantic and Indian Oceans.

As the attempts to solve the question of longitude at sea failed, the king of Spain, in 1598, offered a reward for anyone who came up with a practical solution. This example was soon followed by the Dutch States-General, the governments of France and Venice, and eventually in 1714 by the British Parliament, which offered £20,000. The result was that a great many inventors claimed these prizes. Among those responding was Galileo Galilei, who suggested that the eclipse and occultation of Jupiter's satellites could provide a solution, as they are visible at the same instance for every observer. Lunar eclipse observations to determine longitude were done successfully by astronomer Edmond Halley near the Cape of Good Hope in 1719 and on land by Captain James Cook in Canada in 1766. However, to be successful for navigation, eclipse and occultation observations require great accuracy that, due to the movement of a ship, was almost impossible to accomplish at sea.

For the Royal Society of London for Improving Natural Knowledge (founded 1662) and the Académie Royale des Sciences in Paris (founded 1666), solving the question of how to find longitude at sea was one of the many subjects they engaged. An important step toward this was the founding of the Observatory of Paris in 1667, followed by Greenwich Observatory, near London, in 1675. Both institutions were commissioned to rectify the existing tables of stars in order to find the longitude of places for the use of navigation. Paris Observatory was the first to publish new tables of astronomical data for navigation, such as the daily celestial positions of the sun, moon and planets, and stars, which first appeared in 1678. From 1761 onward the publications also contained lunar tables, which made it possible to find longitude through the aforementioned method of lunar distances. The first accurate lunar tables had been calculated a few years previously by the German mathematician Johann Tobias Mayer. The British astronomer Nevil Maskelyne became the driving force behind the *Nautical Almanac*, which first appeared for the years 1767–1769 and also contained lunar tables. Another condition for using the lunar distance method was an accurate instrument for measuring the distance. That had been fulfilled in

Chinese navigator Zheng He's compass-guided chart to the Persian Gulf.

1731 when John Hadley of London designed the octant (also named Hadley's quadrant), a double-reflecting-angle measuring instrument far more accurate than the mariner's astrolabe and cross-staff. About three decades later it was successfully transformed into the sextant, and later adapted as the reflecting circle.

The method of lunar distances (lunars) was soon firmly established as a reliable method to find the longitude at sea. James Cook was among the first to apply it, in New Zealand in 1769, using the *Nautical Almanac* and a sextant. For many years lunars competed with the method of finding longitude by use of a chronometer. This is a clock that keeps the time on the prime meridian accurately during a voyage, and was developed successfully by the Englishman John Harrison, whose fourth timekeeper was awarded the longitude prize of British Parliament. Until the nineteenth century the astronomical solution by means of lunars and the mechanical method by means of a chronometer were both used at sea. Eventually the chronometer prevailed, because the method to find longitude by that instrument was much simpler than through lunars. An important result of the availability of these methods to find longitude was that sea charts became considerably more accurate.

A clouded sky prevents the taking of a noon observation of the sun, and a weather condition like that can last for days. In the mid-eighteenth century Cornelis Douwes, a teacher of navigation in Amsterdam,

developed the first successful method of double altitudes, taken before and after noon. Hence forward latitude could be found without the restriction of the traditional noon observation of the sun. Douwes's method was improved and remained in use until the nineteenth century, when position line navigation gradually also came into use. This is the name for various methods by which, through an astronomical observation and subsequent calculation and construction in a chart, a ship's position could be found at almost any time of the day. The first to develop a method by which a single observation of the sun or a star resulted in a position line was the American captain Thomas Sumner, in 1843. The intersection of several "Sumner lines," taken from stars in different directions, provided a fix. In the 1860s the Sumner method was improved by French astronomers and naval officers, and by then celestial navigation had reached the level at which it remained until long after World War II.

Electronic Means of Navigation

The development of wireless radio, at the beginning of the twentieth century, opened new possibilities, first through radio direction finding and later through radar and hyperbolic radio systems, such as Decca and loran (long range navigation). With these systems, within certain limitations, a position line or a

fix could be obtained independently of weather conditions. The first practical gyrocompass was invented in 1906, which made north-finding possible without using the Earth's magnetic field.

The next major development was the introduction of satellite navigation in the late 1970s. With the Global Positioning System (GPS), which became fully operational in the 1990s, a position can be obtained instantly, and it is far more accurate than through celestial navigation. As GPS became cheaper and easier to obtain, satellites have now replaced sextants and nautical almanacs completely. The Global Positioning System is operated by the United States government, and to insure independence from this system, the European Union supports and owns the European satellite navigation system, named Galileo, which should be operational around 2014. In the 1980s the electronic chart was developed. This is a digitized chart (a chart of which the image is built up of digits and made visible on a computer screen) that can be linked to other relevant navigational data, including GPS data, the actual water depth found with an electronic echo-sounding device, the ship's speed found with an electronic log, the gyrocompass, and radar-reflected images. In the decades to come, the electronic chart is expected to replace the traditional paper sea chart.

Navigating Airplanes and Autos

In the early years of aviation, airplanes were navigated by visual reference to the ground. As altitudes increased, "blind flying" (in clouds) became unavoidable, and various means of radio navigation were introduced. Most were non-directional radio beacons, and airplanes would fly from beacon to beacon. In the 1920s, the air plot technique, to find a dead-reckoned position, was derived from nautical practice. The first air almanac appeared in 1933, and five years later the first astronomical tables for air navigation were published.

In the 1940s sextants fitted with artificial (bubble) horizons were introduced, and a fix was found with celestial altitudes and the use of an air almanac

and astronomical tables. Short-cut methods for calculation were developed especially for aviation, as were navigating machines and navigational slide rules, such as Bygrave's cylindrical slide rule, which bypassed or skipped part of the calculation. During World War II radio navigation was further improved. For civil aviation, non-directional beacons remained in use over land, and for crossing oceans and deserts traditional celestial navigation was applied. After the War loran was used in civil aviation for crossing oceans, as were radio signals from dedicated ocean station vessels. During the 1960s, non-directional beacons were gradually replaced by VOR (Very high frequency Omnidirectional Range) stations; special techniques for polar navigation were already applied since 1957.

Due to the increase of aircraft in the 1960s and the introduction of jet aircraft, the requirements for position reporting became more stringent. Over land the use of ground radar by air traffic control increased but long-range (en route) navigation remained basically unchanged, although sextants were improved.

Inertial navigation was developed for civilian en route aviation use in the 1970s, replacing celestial navigation. At present, GPS is also seeing civilian use and expectations are that it will be playing an ever increasing role in future aviation.

Isaac Newton was the dominant figure in the Scientific Revolution, a creative period of experiment, observation, and theory that began in the mid-sixteenth century. Newton remains an icon of the scientific method, even for nonscientists who only vaguely know what he accomplished—for instance, the formulation of the theory of universal gravitation and the invention of calculus.

According to many historians, a revolution in scientific thought began when astronomers learned about the theory of Nicolaus Copernicus (1473–1543)—that the Earth revolved around the sun—which he proposed in a book published shortly after his death. Isaac Newton was the dominant figure in that Scientific Revolution (c. 1550–1700), and by the time of Newton’s own death, Copernicus’s theory had transformed western Europe’s understanding of the universe. Other than Charles Darwin (1809–1882) and Albert Einstein (1879–1955), Newton remains the world’s most widely known scientist, an icon of the scientific method. Newton himself was dissatisfied with his achievements, as they explained only certain aspects of the universe. Much more ambitious, he searched vainly for a single system that could explain everything, a unified system of the universe. Nor was he satisfied with learning merely *how* things happened; he wanted to know *why*.

Clearly unfit for the life of a farmer, Newton was sent by his family from its Lincolnshire farm to Cambridge University. He did not immediately impress his teachers there. He spent the most creative period in his life back in Lincolnshire when he temporarily left the university to escape an outbreak of plague. Nearly all his ideas originated during these eighteen

Sir Godfrey Kneller, *Portrait of Isaac Newton* (1689). Farleigh House, Farleigh Wallop, Hampshire.

months in 1665 and 1666. Newton fits the stereotype of the hermit scholar who lived in isolation for no purpose other than work. When Cambridge appointed him a professor of mathematics, he proved to be a poor teacher. He won respect (and election to the prestigious scientific Royal Society) when he built an impressive reflecting telescope.

In an age before specialization, Newton contributed to diverse fields of the physical sciences and mathematics. Often “publication” in private correspondence preceded print publication by many years. As a young

If I have seen further, it is by standing on the shoulders of giants. • Isaac Newton (1642–1727)

man, Newton began his study of color and light, which reached a climax with the publication of the *Opticks* in 1704. While still very young he developed the mathematical theory that he called the method of fluxions (later known as calculus). Concurrently, the German scholar G. W. Leibniz (1646–1716) developed differential and integral calculus. A bitter controversy followed: did Newton or Leibniz deserve the credit? They had worked independently, so the answer is both of them. Newton is best known for his theory of universal gravitation. According to a familiar but probably untrue story, it was when he saw an apple fall from a tree in the family orchard that he was inspired to recognize that the same forces, expressed in the same laws, controlled both earthly and celestial bodies. Written in Latin and published in 1687, Newton's major work on mechanics was the *Principia* (or *Mathematical Principles of Natural Philosophy*).

Although he engaged in unattractive quarrels with scientists who dared dispute the correctness or the originality of his ideas, he acquired more admirers than critics, both inside and outside the English scientific community. He briefly served in the House of Commons, and in 1696 he moved from Cambridge to London when patrons put him in the Royal Mint at a salary that made him rich. In 1703 Newton was elected president of the Royal Society, and in 1705 he was knighted. One of his very few close friendships appears to have been that with the young Swiss mathematician Nicolas Fatio de Duillier (1664–1753), in the early 1690s. Never married and suffering recurrent bouts of depression, Newton in his later years lived quietly with a niece. His religious views were unorthodox—he rejected the divinity of Jesus Christ—but, because these views were not fully known, he did not experience the persecution that his great predecessor Galileo (1564–1642) had suffered.

Although the reclusive Newton never traveled outside his native England, his work became accepted in much of Europe, but not all of it and not immediately or unanimously. For instance, Jesuit scholars remained loyal to the older Cartesian system, devised by René Descartes (1596–1650). His vortex theory credited impulsion in particles themselves (and not

attraction) with moving things around in the universe. Newton eventually won acceptance because his theories produced better practical results. For instance, his theory correctly predicted the return of Halley's comet. During the middle decades of the eighteenth century the French *philosophes* Voltaire (1694–1778) and Gabrielle Emilie le Tonnelier de Breteuil, Marquise du Châtelet (1706–1749) popularized Newton's ideas outside England among educated readers. Du Châtelet translated Newton's *Principia* into French and wrote a commentary describing new proofs of Newton's theories. Aided by Newton's prestige, the natural sciences became the model for the social sciences in the Enlightenment, with the latter borrowing the self-confidence that the former had earned. Still later, Eurocentric interpreters of world history adopted Newton and the concept of a scientific revolution as evidence for the superiority of the West.

Eventually, scientists throughout the world acknowledged Newton as their teacher and inspiration. For instance, by 1730 Jesuit missionaries brought some of Newton's astronomical ideas to China, and by the middle of the nineteenth century Newton's calculus and part of his *Principia* were available in Chinese.

In the 1930s a reaction against the old emphasis on individual genius as the explanation for scientific progress challenged Newton's importance. Marxists and others argued that science was a collaborative enterprise, influenced by contemporary ideology, and that the acceptance of new scientific ideas by nonscientists required an educated public. More recently, scholars pointed out that Newton had “unscientific” interests, including alchemy—turning base metals into gold—and biblical chronologies and prophecies. In fact, all of Newton's work was interrelated. It is inadequate to describe him as a scientist, a modern term. A man of his own times, he was a cosmologist who sought to understand everything as a single system. He remains a powerful symbol of the new science that eventually changed the world.

Nkrumah, Kwame

(1909–1972)

FIRST HEAD OF INDEPENDENT GHANA

Formerly known as the Gold Coast, Ghana was the first sub-Saharan African colony to win independence (in 1957) from European colonial rule, providing a model for other aspiring African states. Under Kwame Nkrumah's leadership, Ghana promoted a firm anti-imperialist foreign policy focused on creating pan-African political and economic unity in a "United States of Africa."

Independent Ghana's first leader, Kwame Nkrumah, was born in 1909 near the modern border between Ghana and Côte d'Ivoire. Established less than ten years earlier, this international boundary split the Nzima people, to whom Nkrumah belonged, between two different countries. The arbitrary nature of the borders of modern African states remains a major colonial legacy, and was a problem Nkrumah dealt with directly later in life through unification policies, which proposed redrawing African borders. Lucky to receive an education, Nkrumah eventually attended the Government (teacher) Training College. Here he was introduced to the ideas of the Jamaican Pan-Africanist Marcus Garvey (1887–1940). Garvey's writings emphasized the links between all people of African descent and the need to build an African Nation. It was also at college that Nkrumah became interested in going to the United States. He left the Gold Coast in 1936, but went first to London. While in London, Nkrumah learned of Ethiopia's defeat by the Italian Fascists. Years later Nkrumah said that at that moment he felt "as if the whole of London had declared war on me personally" (Nkrumah 1957, 27). The Italian invasion of

Kwame Nkrumah, an advocate of Pan-Africanism.

the last independent state in Africa was seen as an outrage throughout the black world. It clearly connected imperialism to war and highlighted the exploitation of Africa under European colonial rule. It was in this context that Nkrumah arrived in the United States.

While in the United States, Nkrumah began to link the racism experienced by U.S. blacks to the colonial relationships experienced by blacks in Africa and the Caribbean. He graduated from Lincoln University in Pennsylvania in 1939 and entered the PhD program in philosophy at the University of Pennsylvania, where he published his anti-imperialist ideas more widely in a student paper, *The African Interpreter*. Nkrumah became involved in politically organizing Africans

Our colonial past and the present day intrigues of Neo-colonialism have hammered home the conviction that Africa can no longer trust anybody but herself and her resources. . . . We in Africa must learn to band together to promote African interests or fall victims to imperialist maneuvers to recolonize us. • Kwame Nkrumah (1909–1972)

abroad through the Pan-Africanist movement. His dissertation, entitled *The Philosophy of Imperialism, with Special Reference to Africa*, was never accepted by the university; Nkrumah believed he was the victim of political censorship. In 1945 Nkrumah went to London to study law and perhaps to finish his doctoral dissertation. However, he quickly became immersed in the organization of the upcoming Fifth Pan-African Conference, which was to be held in Manchester and chaired by one of his heroes, W. E. B. Du Bois (1868–1963). The contacts Nkrumah made while working on this project formed a “who’s who” list of future nationalist and anti-imperialist leaders across Africa. His work on the conference attracted the attention of the United Gold Coast Convention (UGCC), whose leaders invited Nkrumah to return to Ghana to become the secretary of the party in 1947.

Nkrumah quickly fell out with the moderate UGCC and established the Convention People’s Party (CPP) in 1949. Demanding “self-government now,” the CPP launched strikes, boycotts, and civil disobedience based on Mohandas Gandhi’s satyagraha (nonviolent resistance) methods. Jailed in 1950 for his political activities, Nkrumah was released after winning a seat in the legislative assembly from prison in 1951. This event marked the beginning of the end of British rule in the Gold Coast, although formal independence—and the name Ghana—did not come until 1957. Nkrumah was elected prime minister of the Gold Coast in 1952 and served until 1960, when he became president of Ghana. While in power he promoted an African version of socialist development and an anti-imperialist foreign policy. He was active in the nonaligned movement, which established alliances amongst former colonies as alternatives to the bipolar Cold War visions promoted by the United States and the Soviet Union. In 1963, coinciding with the formation of the Organization of African Unity (OAU), Nkrumah published *Africa Must Unite*, outlining his argument for unification. But the OAU

At the reception following the inauguration of President Kwame Nkrumah (Accra, Ghana, 1 July 1960), Nkrumah (left), stands with W. E. B. Du Bois and Shirley Graham Du Bois. Du Bois Central, UMass Amherst Library.

rejected Nkrumah’s model, Ghana’s economic condition declined, and unrest spread. In 1964 Nkrumah forbade political opposition, establishing the CPP as the only party in the first of many African one-party states. He attributed some of Ghana’s problems to interference by the CIA, but understood that most of the nation’s problems were economic. In 1965 he published an analysis of the role of foreign investment in maintaining colonial relationships in new forms in Africa; it was called *Neo-Colonialism: The Last Stage of Imperialism*. Although astute in his analysis of Africa’s economic relations with the rest of the world, Nkrumah had lost touch with Ghanaians suffering from poor local economic conditions. Nkrumah’s political enemies multiplied and in 1966 he was overthrown in a military coup d’état. He lived in exile in Guinea until his death in 1972. Controversy will continue to surround Nkrumah’s legacy, but his understanding

of the interaction between Africa and the global economy via colonialism offers fresh insight into world history from an African perspective.

Nonviolence

Nonviolence, the Indian nationalist leader Mohandas Gandhi said, “Is as old as the hills.” As an idea and an ideal, nonviolence is indeed old. Throughout history people have yearned for harmony, peace, and stability—conditions ultimately rooted in nonviolence—and have been inspired by the nonviolent activism of such leaders as the Dalai Lama, Corazon Aquino, Cesar Chavez, and Lech Walesa.

People have often tried nonviolent means to redress their grievances. But the idea of nonviolence as a deliberate and preferred strategy of action for political and social change acquired widespread credibility and currency only during the twentieth century. No person was more central to that credibility and currency than Mohandas Gandhi. With Gandhi nonviolence assumed a revolutionary dimension unprecedented in scope and global impact.

Gandhi and the Power of Nonviolent Action

Mohandas K. Gandhi (1869–1948) was the first person to develop a coherent worldview of nonviolent action and to propose a well-articulated strategy to realize such a worldview. Gandhi’s strategy was to struggle using a moral force. He called this force “satyagraha”—the active pursuit of truth through love and nonviolence. A *satyagrahi* (a person who undertakes satyagraha) must renounce not only violence, but also revenge and hate. Gandhi’s dedication to nonviolence is unparalleled in the history of nonviolent mass action.

Gandhi’s initial experiments in satyagraha were in the context of South Africa’s policies of racial

गंधीजी (1939)

New York Public Library.

discrimination at the dawn of the twentieth century. He subsequently used satyagraha to transform economic, political, and social realities in British colonial India. To him the purpose of satyagraha was not to force one’s adversaries into submission but rather

to transform the interrelationships of those people engaged in conflict. Gandhi's campaigns relied on methods such as fasting, *hartal* (strike), noncooperation, boycotts, marches, and civil disobedience and were aimed at the injustices of British colonialism as well as the moral failure among Indians. For instance, he undertook nonviolent campaigns to relieve the peasants of Champaran of the economic exploitation of British planters (1917–1918); to free India from British rule (1920–1921, 1930–1934, 1940–1942); and to foster unity and heal tensions between Hindus and Muslims (1947–1948) during and after partition of the subcontinent into India and Pakistan.

Gandhi's demonstrations of satyagraha—both in spirit and strategy—touched people around the world and inspired hundreds of leaders across geographical, ethnic, racial, and religious boundaries. Many people who followed Gandhi on the path of nonviolent action, even if pursuing different trajectories, have been internationally acclaimed. These people include the Indian freedom fighter Vinoba Bhave; the Dalai Lama (spiritual and political leader of Tibet); South African Archbishop Desmond Tutu; U.S. civil rights leader Martin Luther King Jr.; U.S. farm worker activist Cesar Chavez; Aung San Suu Kyi, a prodemocracy activist in Myanmar (Burma); Polish trade union activist Lech Walesa; and Czech political activist Vaclav Havel. After Gandhi, nonviolent action became a powerful trend during the twentieth century and shaped scores of social and political movements around the world.

Nonviolent Struggles in Asia

In Asia people used nonviolent action to combat oppression arising from colonialism or authoritarian regimes and to mobilize support for democratic reform and human rights. Khan Abdul Gaffar Khan (1890–1988), later known as “Badshah Khan” or “Frontier Gandhi,” was a Muslim leader of the Pathan people in the North West Frontier Provinces (NWFP) of India. He was a follower of Islam and with Gandhi and founded the world's first nonviolent army, known as the “Khudai Khidmatgars” (Servants of God), to

protest British atrocities, including plundering of Pathan villages. The army eventually grew to a force of eighty thousand Pathans dedicated to nonviolent action. Badshah Khan supported Gandhi's vision of a united India. However, partition could not be avoided, and NWFP became part of Pakistan. With the support of Khudai Khidmatgars, Badshah Khan mobilized a nonviolent movement to gain democratic rights for the Pathans in newly created Pakistan. During the next three decades he spent fifteen years in prison and seven years in exile as Pakistan continued to be ruled by the military.

Khudai Khidmatgars is significant not only because of its struggle against colonialism and authoritarianism, but also because it was an experiment that helped advance the agenda for a peace army to resolve international conflicts. Moreover, because of the dedication of such large numbers of Muslims to nonviolent action, the Khudai Khidmatgars helped to dispel the myth that nonviolence is not consistent with Islam.

Tibetan Quest for Freedom

Tenzin Gyatso (b. 1935), the fourteenth Dalai Lama, was forced into exile by the Chinese government in 1959. The Dalai Lama continues to lead his followers in nonviolent resistance against the Chinese and to serve as a beacon of nonviolence to the international community. He has declared that violence by Tibetans would be suicidal and that “nonviolence is the only way” for Tibet to gain independence. While accepting the Nobel Peace Prize in 1989, the Dalai Lama commended nonviolent resistance, including the hunger strikes of Chinese students at Tiananmen Square in Beijing. The Dalai Lama, like Gandhi, believes that the cultivation of inner peace and integrity is the ultimate weapon for world peace because happiness lies within oneself.

Restoring Democracy in the Philippines

Corazon Aquino (1933–2009) led a nonviolent resistance to restore democracy in the Philippines after President Ferdinand Marcos illegally declared himself the winner of an election in 1986. Influenced by Gandhian tactics of boycott and noncooperation, Aquino

Dr. Martin Luther King Jr. and Mathew Ahmann at the March on Washington, 28 August 1963. National Archives.

called for a nationwide boycott of banks, newspapers, beverages, and movies. She called upon people to withdraw their funds from large banks with close connections to Marcos, to shut down schools and factories, and to delay paying utility bills. Tactics of noncooperation brought government operations to a halt and slowed the economy. Housewives, priests, workers, and businesspeople alike supported the movement, refusing to accept the fraudulent outcome of the election. The force of nonviolent sanctions and boycott ultimately prevailed: Marcos was exiled to Hawaii, and Aquino became the duly elected president of the Philippines.

Quest for Democracy in Myanmar

In 1988, two years after democracy was restored in the Philippines, Aung San Suu Kyi (b. 1945) led a democratic movement in Myanmar (Burma). Consequently, in 1990 elections were held in which Suu Kyi's democratic party won. However, unwilling to give up authority, the military junta refused to abide by the election results. Inspired by Gandhian satyagraha and Buddhist compassion, Suu Kyi continued her nonviolent struggle in the face of oppression and remained committed to the cause of freedom and human rights even when put under house arrest. Her resistance often takes the form of hunger strikes and

active noncooperation with the authoritarian regime because she is convinced that "freedom from fear" is essential for bringing democracy to Myanmar. Large numbers of Myanmar citizens are influenced by the moral strength of Suu Kyi and regard her as Myanmar's destiny.

Arrested Democracy in China

After the emergence of a democratic movement in Myanmar, in China tens of thousands of college students, led by student Wu'er Kaixi (b. 1968), demanded democratic reform from the Chinese Communist government in 1989. As the movement gained momentum, three thousand students staged a hunger strike, drawing more than a million people to their side at Tiananmen Square. They demanded democratic reform and an immediate meeting with government officials. But negotiations did not continue because students felt rising anger toward the government and because student leaders felt estranged from one another. On 4 June 1989, military troops marched into the square, killing several hundred protesters in what became known as the "Tiananmen massacre." However, the movement helped secure international condemnation of the Chinese Communist regime for its violation of human rights and resulted in the imposition of economic sanctions.

Non-violence leads to the highest ethics, which is the goal of all evolution. Until we stop harming all other living beings, we are still savages. • **Thomas A. Edison (1847–1931)**

Nonviolent Movements in the Americas

In the Americas nonviolent movements became central to the restoration of rights in the United States—the world’s most powerful democracy—and to the defeat of dictators in central and Latin America.

Civil Rights Movement in the U.S. South

The seeds of Gandhian nonviolence were planted in new soil when Martin Luther King Jr. (1929–1968) led the civil rights movement in the U.S. South during the 1950s and the 1960s. Drawing upon satyagraha and his own experience as a Christian minister, King developed a unique philosophy of nonviolent resistance that was effective during the major civil rights campaigns, including the Montgomery, Alabama, bus boycott (1956), the lunch counter sit-ins (1960), the freedom rides (1961), the Albany, Georgia, campaign (1961–1962), the Birmingham, Alabama, campaign (1963), and the drive for voting rights (1964–1965). The movement championed the use of nonviolent action as a form of social protest and mobilized the African American population across the nation. King’s speech at the Lincoln Memorial in Washington, D.C., in 1963, during which he articulated his dream of racial equality, attracted the largest nonviolent demonstration after Gandhi’s mass movement in India and helped bring about the Civil Rights Act of 1964 and the Voting Rights Act of 1965.

United Farm Workers Movement

While the civil rights movement was still in its infancy, a young Mexican American farm worker, Cesar Chavez (1927–1993), was searching for a solution to his community’s economic problems. He found a sense of direction in Gandhi’s autobiography, *The Story of My Experiments with Truth*. Imbued with the spirit of satyagraha, energized by King’s civil rights campaigns, and drawing upon his Christian ethic, Chavez during the period 1960–1980 led members of the United Farm Workers (UFW) of America in nonviolent campaigns to secure their rights and protest their exploitation. Through policy changes and legislation

Chavez achieved numerous improvements, such as an increase in wages, work rule reforms, workers’ benefits, and a ban on the use of dangerous pesticides on farms. The movement relied on nationwide consumer boycotts and labor strikes, pickets, processions, and fasting. The movement not only achieved its goals, but also demonstrated the power of an underclass that previously had had no political standing.

Civic Strike in El Salvador

After people discovered the power of nonviolence, the scope of its application assumed several dimensions. In El Salvador in Central America students, doctors, and merchants in 1944 used nonviolent action to bring down the longtime military dictator, General Hernandez Martinez. Opponents of Martinez’s brutal policies organized a civic strike using nonviolent tactics. They detached Martinez from his closest friends, allies, and members of the military and forced him into exile.

Desaparecidos Movement in Argentina

In 1977 fourteen mothers organized a march in Buenos Aires, Argentina, with the motto, “We will walk until we drop.” Wearing white scarves, these women in their sixties, seventies, and eighties fearlessly walked into the Plaza de Mayo and were joined by hundreds of other people in their protests against the “disappearance” of their sons, daughters, husbands, and other relatives under the authoritarian regime of General Jorge Videla. Marching, writing letters to international agencies, advertising in newspapers, and collecting twenty-four thousand signatures on a petition, members of the *desaparecidos* (the disappeared) movement created international awareness about the violation of human rights in their country while refusing to be silenced at any cost. Their efforts eventually led to the downfall of the military government.

Chilean Resistance to a Dictator

Like protesters in El Salvador and Argentina, protesters in Chile remained committed to nonviolent noncooperation as they opposed the dictatorship of General Augusto Pinochet (1915–2006). As the protest movement grew, protesters gained courage and

refused to pretend that Pinochet had their consent to rule. On the contrary, they worked to convince people that Pinochet commanded no popular support of Chileans. Challenged by such protests in 1988, Pinochet called for plebiscite (vote), which he lost. Clinging to authority, he tried to bypass the plebiscite results. But his own supporters, in the wake of mounting popular protest, refused to support him, and he was defeated.

Poland, Czechoslovakia, and Revolutions in Europe

During the last two decades of the twentieth century nonviolent revolutions became a major trend throughout Eastern and Central Europe. The most notable took place in Poland and Czechoslovakia.

In Poland, Lech Walesa (b. 1943), inspired by Gandhi, led industrial strikes in 1980, giving rise to Solidarity, a federation of Polish trade unions. The ensuing movement during the next several years remained totally nonviolent. It not only brought an end to Communist dictatorship in Poland but also kindled the spirit of democracy throughout eastern Europe. Through his dedication to nonviolent action, Walesa shared a lesson he had learned: "We can effectively oppose violence only if we ourselves do not resort to it." Walesa became the president of Poland in 1990.

In Czechoslovakia, the writer Vaclav Havel (b. 1936) led the nonviolent resistance movement against Soviet oppression. His seminal essay, "Power of the Powerless," outlined a strategy for nonviolent revolution. He called upon people to empower themselves by daring to "live within the truth" and refusing to "live a lie." Havel was elected first as president of Czechoslovakia in 1989 and later as first president of the new Czech Republic in 1991. Soon "people power" had resulted in the fall of the Berlin Wall and the overthrow of Communist regimes all over Eastern Europe.

South Africa: A Country of Struggle

Even though Gandhi had begun his satyagraha in South Africa, inspiring nonviolent action throughout

the world, South Africa remained under the policy of apartheid (racial segregation) for most of the twentieth century. The struggle against apartheid assumed violent dimensions several times during the century. Even the political leader Nelson Mandela (b. 1918), who began the nonviolent resistance, took to violence, resulting in his serving twenty-three years in prison. Nevertheless, nonviolent sanctions, strikes, rent boycotts, street committees, and boycotts of business owned by whites ultimately disabled the government. Moreover, the formation of the United Democratic Front, which included all people who favored democratic reforms through nonviolent means, eventually forced change in South Africa. Nonviolent methods alone did not bring the change, but they were instrumental in exposing the stark nature of apartheid and the suffering of people engaged in nonviolent resistance. Such exposure undermined the credibility of the government. In 1994, after free elections, South Africa finally became a democracy; Mandela was its first president.

Outlook

Nonviolence emerged as a powerful trend during the twentieth century. Undertaken in diverse contexts, nonviolent movements varied widely in the degree of challenge they posed to the established institutions of power and authority and the extent to which they brought about meaningful social transformation. However, collectively they showed that war and violence are not the only, and certainly not the best, means of changing the institutions of power or creating a new social order. In the years to come we may see that Gandhi was right in asserting that "we are constantly being astonished at the amazing discoveries in the field of violence. But I maintain that far more undreamt-of and seemingly impossible discoveries will be made in the field of nonviolence."

North Atlantic Treaty Association (NATO)

After World War II, relations were strained among Allied powers, and the Soviet Union's encroachment in Europe signaled the coming Cold War. Twelve countries signed the North Atlantic Treaty in 1949 and formed the North Atlantic Treaty Organization (NATO) to restore and maintain the security of democracies on both sides of the Atlantic. As of 2010 NATO has twenty-eight member countries.

The North Atlantic Treaty Organization (NATO) was created as result of the signing of the North Atlantic Treaty on 4 April 1949 "to restore and maintain the security of the North Atlantic area" (defined as territories, islands, vessels, and aircraft of the signatories "north of the Tropic of Cancer"). Its creation has to be considered in the context of the incipient Cold War that developed due to deteriorating relations among the victors of World War II, with the former Soviet ally perceived as an increasing threat to the safety of democracies on both sides of the Atlantic. The explosion of the first Soviet atom bomb on 29 August 1949 confirmed that perception. The treaty was also drawn up to avoid repeating the mistakes that followed World War I, when the four major Western victors (France, Italy, the United Kingdom, and the United States) each went their own way without a mutual guarantee of their future safety.

Winston Churchill was probably the first statesman to fully understand the implications of the Red Army's advance into the heartland of Europe agreed upon at Yalta. The combination of a residual U.S. army and air force occupying southern Germany, nonexistent French and Italian armored and air forces, and a limited British land army on the Rhine

(Britain being traditionally strong on the seas and now in the air) could under no circumstances resist a Soviet attack beyond what Churchill had then called the Iron Curtain. The British policy of trying to persuade the United States to abandon its prewar isolationism met at first with little success. Down from over 3 million men stationed in Europe in May 1945, the United States presence was less than four hundred thousand strong—smaller than the British contingent—in the spring of 1946, when Churchill raised the alarm again in a speech on "The Sinews of Peace" given before President Truman at Fulton, Missouri. The speech got a very cold reception in the American press.

The deciding factor was probably the British inability to continue to support the Greek government's struggle against Communist guerillas in March 1947, which made it clear that only the United States had the resources in men, equipment, and money to contain Communist expansion—in Europe as in the rest of the world. The approval by Congress in that month of the "Truman Doctrine," whereby the United States undertook "to support free peoples who are resisting attempted subjugation by armed minorities, or by outside pressure," was a major reversal of policy, and was soon extended from Greece to most of western Europe. The Marshall Plan, announced in June 1947, was in the same vein, postulating that European economic recovery with American aid was the best bulwark against Soviet and other Communist expansion. These American initiatives accorded with the ideas publicly expressed by Belgian, British, and French statesmen, that only a common system of defense could guarantee the safety of western Europe. The plea became increasingly urgent with the Prague

coup of 22 February 1948, after which events moved very fast.

A treaty of mutual assistance between Belgium, France, Luxembourg, the Netherlands, and the United Kingdom was signed in Brussels on 17 March 1948, with the Canadian prime minister expressing interest in joining them on 28 April, and Senator Arthur H. Vandenberg of the United States initiating talks in the Senate that resulted in the almost unanimous adoption on 11 June of a resolution calling for “the association of the United States, by constitutional process, with such regional and other collective arrangements as are based on continuous and effective self-help and mutual aid, and as affect its national security.” The road was clear for formal negotiations and the drafting of a treaty, which took place in Washington from 6 July 1948 to 18 March 1949, when the terms were made public, with the Brussels Treaty signatories, Canada, and the United States announcing that they had also asked Denmark, Iceland, Italy, Norway, and Portugal to join the proposed alliance and that they had accepted. (Spain only joined in 1982, after the death of Francisco Franco.)

These nations constituted the twelve founding members, with Greece and Turkey joining in 1952. The controversial accession of the Federal Republic of Germany in 1955 led to the creation of the Warsaw Pact—the Soviet Bloc’s version of the Atlantic alliance—and extreme tension with Communist parties in Western Europe, which denounced the rearmament of “revanchist” (i.e., intent on starting another war avenging the defeat of 1945) crypto-Fascists, as they saw the West German governing elite. The 1960s saw another period of difficulty for NATO, over the question of the “American nuclear umbrella” and who would decide on nuclear war. Only two other members, the United Kingdom (1952) and France (1960), had a nuclear retaliation capacity—though it was in no way comparable to that of the two superpowers—and each chose a different course, with the British government opting for total integration of its nuclear deterrent (1962) while France, under General de Gaulle and his successors, decided that continued

membership in NATO did not preclude independent nuclear strikes (1966). After the period of detente in the 1970s, the installation of American cruise missiles on European soil in the 1980s led to many anti-NATO demonstrations, notably in England.

Many predicted that the fall of the Berlin Wall (9 November 1989) and the consequent removal of the Communist menace would lead to the dissolution of NATO, which had been negotiated and established against the backdrop of the Berlin blockade and airlift (24 June 1948–4 May 1949), but the organization seems to have found a new lease on life, with action in Serbia in 1994 and the Middle East in 2004, and the accession in 1999 of the Czech Republic, Hungary, and Poland, followed in 2004 by that of the Baltic Republics (Estonia, Latvia, and Lithuania) and Bulgaria, Romania, Slovakia, and Slovenia, and in 2008 by Albania and Croatia. The former anti-Communist, anti-Soviet alliance may still be said to justify its mission “to restore and maintain the security of the North Atlantic area” in the face of new threats against the twenty-eight sovereign states that are members as of 2010.

For over a thousand years, from the fourth century to the fourteenth century CE, the medieval Nubian kingdoms and their peoples dominated a wide span of Africa, stretching 1,200 kilometers from the plains of the Blue Nile (present-day Sudan) in the south to Aswan, Egypt, in the north.

The historical roots of the Nubians in Africa trace back to a set of once widespread pastoralist communities, called the Astaborans by modern-day scholars. These peoples occupied the dry steppes of the eastern Sahara in the fifth and fourth millennia BCE. The ancestral Nubian-speaking society arose out the breakup of the Astaboran group during the final drying out of the Sahara in the middle of the third millennium BCE. The earliest surviving written notices, from two thousand years later, describe the Nubians of the third and second centuries BCE as living west of the Nile along the southern Sahara fringes, where they formed several small kingdoms independent of the powerful empire of Meroë. By the first and second centuries CE, a few Nubian communities had moved east of the river, while larger numbers settled along the Nile itself between the first and fifth cataracts. In these lands the Nubians became subjects of the Meroitic Empire. Some scholars propose that the Meroites may even have encouraged the Nubians to settle down as a buffer farming population along the Nile, after the border between the Roman and Meroitic territories had been established by treaty near Philae in 23 CE.

The Rise of the Nubian Kingdoms

With the collapse of Meroitic power in the third and fourth centuries, a period of strife overtook the region

between Aswan and the Blue Nile to south, with the Nubians emerging triumphant by the later fifth and early sixth centuries. Archaeological findings identify two Nubian societies along the Nile, one between the first and third cataracts and the second extending from the third cataract south to the Blue Nile regions. In the sixth century these territories were apparently divided among three kingdoms: Nobadia, with its capital at Faras, Makuria, with its capital at Dongola, and Alodia farthest south, with its capital at Soba (south of present-day Khartoum). Interestingly, the royal succession in these kingdoms was matrilineal, the normal pattern being for a nephew to succeed his mother's brother as king.

From the 540s to the 560s, missionary activities converted the Nubian royal courts and, in time, the general Nubian populace to Christianity, although some Nubians had become Christian as early as the fifth century. Nobadia and Alodia accepted Monophysite teachings (that Christ had a single divine-human nature; modern-day Monophysite churches include the Coptic and Ethiopian Orthodox churches), but Makuria apparently initially followed the Chalcedonian creed (which stated that Christ had two distinct natures, divine and human, in one person; this is the position adopted by the Roman Catholic, Eastern Orthodox, and, later, the Protestant churches).

The traditional view of historians has been that, sometime before 707 CE, Makuria conquered and incorporated Nobadia. But a recent reevaluation of the literary and linguistic evidence by linguist-historian Marianne Bechhaus-Gerst strongly suggests that the unification of Nobadia and Makuria took place by early in the 600s. Moreover, her work shows compellingly that Nobadian culture dominated the

*It flows through old hushed Egypt and its sands, / Like some grave mighty thought
threading a dream.* • From “The Nile,” by Leigh Hunt (1784–1859)

unification of the two kingdoms. The language of Nobadia, known as Old Nubian, became the written and administrative tongue of the combined state, and Nobadia's Monophysite faith became the established religion, displacing Makuria's earlier adherence to Eastern Orthodoxy.

The social history evinces a similar history. The Nobadian stretches of the river were home to a multilayered social formation, with an administrative class, a prospering merchant class, a clerical class, servants and artisans in the towns, and a class of peasant farmers on the land. In contrast, society in the former Makuria appears to have consisted primarily of just two strata, the ruling and administrative elite and its retainers, and a far larger, probably enserfed peasant majority. The old lands of Makuria, in other words, bear all the earmarks of a conquered territory ruled by the Nobadians. Outsiders called the new combined state “Makuria,” because its main capital was the Makurian city of Dongola. But the choice of Dongola as the capital most likely reflects an early policy of concentrating state power where opposition was most likely to arise.

The Muslim conquest of Egypt (639–641 CE) and the subsequent Muslim invasions of northern Nubian areas in 642 and 652 CE mark a major transition in the history of the Nubian states. Makuria effectively turned back both invasions. The treaty of peace that ended hostilities established at first a regular annual, and then, after 835 CE, a triennial exchange of goods between Makuria and the governments of Egypt that lasted until the later thirteenth century. Muslim interpretations in much later times sought to portray the relationship as a tributary one. But the contemporary evidence shows this to have been a treaty among equals. Over the next several centuries, although there were a number of outbreaks of war between the Makurians and their northern neighbors, the Nubian states appear generally to have prospered. In the tenth century, Nubian kings in fact intervened in Upper Egypt on behalf of Coptic Christian coreligionists and ruled southern Egypt for several decades. It is clear that through much of this period the Makurian state and its merchant class continued to be prosperous

participants in trade northward to Egypt. From the ninth through the twelfth centuries its kings also undertook to control overland access eastward to the expanding commerce of the Red Sea, launching military campaigns when necessary to maintain a loose hegemony over the nomadic Beja inhabitants of the intervening areas.

Alodia, the Nubian kingdom about which we know the least, was generally reckoned the more powerful of the two states, and it was certainly the more populous and probably the wealthier of the two. Travelers to Soba, the capital city, describe a wealthy court and a thriving urban sector with important trade links to the Red Sea. Among the notable products of country in its heyday was gold, mined in the southeastern borderlands of the kingdom, near the edges of the Ethiopian highlands. While the northern kingdom ruled primarily over people of Nubian language and culture, Alodia was very much a multi-ethnic state, with a variety of other peoples besides Nubians making up its population, especially in most of the peripheral areas of the state. Alodia was too far south to be involved in conflicts with Egypt, but we suspect that its kings, like those of Makuria, must have had very important relations with the Beja, whose lands lay between them and the Red Sea entrepôts. The existence in the tenth and eleventh centuries of several small, nominally Christian principalities among the Beja surely reflects the political and material preeminence of Nubian influences.

Decline of the Nubian Kingdoms

From the twelfth century two new factors began to shift the balance of power away from the Nubian kingdoms. The factor of greatest long-term effect was the emergence and spread of a new ethnic element, Bedouin Arabs, who infiltrated southward from Egypt through the areas east of Nile. In the fourteenth and fifteenth centuries these Arabs began increasingly to displace or absorb the earlier Nubian and related Daju pastoral peoples of the desert steppes along the southern Sahara fringes, spreading a competing religion, Islam, as well a new ethnicity, language, and economy

over large areas. The key to their success may have been that they introduced the first full-fledged camel nomadism into the most marginal areas, before then precariously dependent on goat and sheep raising. Another complicating factor in the thirteenth and fourteenth centuries was the disappearance of the earlier Beja principalities of the Red Sea hills and in their place the rise of a new confederation of Beja clans, the Hadariba, at the same time as Islam increasingly began to take hold among them. Controlling the crucial trade routes between the Red Sea and the old Alodia heartland, the Hadariba appear to have siphoned away a growing portion of the wealth of the trade. By as early as the mid-1200s the Alodia kingdom, which most strongly faced these new pressures, may have begun to break up into a number of independent principalities.

The second factor in the decline of independent Nubia was political. The new Ayyubid rulers of twelfth-century Egypt, instituted policies of more active engagement with the regions to the south, and did the Mamluks after them. These pressures came to a head in the latter half of the thirteenth century and in the early fourteenth century, as aspiring Christian

Nubian rulers undermined their own political base by seeking help from Muslims in their internal struggles for political advantage. In 1324 a new Muslim kingdom of Makuria took power at Dongola. The old Nobadian regions to the north broke away and may have had Christian rulers of their own for several decades longer, as did a number of the small independent Nubian principalities to the south, left over from the breakup of Alodia.

By the beginning of the sixteenth century, however, the political and cultural worlds of the Nubians had changed irretrievably. In 1504 the region encompassing the former territories of Alodia and the southern part of Makuria was united into a new state, the Funj kingdom, with its capital at Sinnar, 200 kilometers south of the now ruined city of Soba. The new rulers opted for Islam as the religion best able to unite their populations and consolidate their trade relations with the Red Sea countries and Egypt. Nubian languages continued to be spoken, especially in the old territories of Makuria. But Arabic became the language of commerce and, in time, of administration, in the Funj kingdom, and gradually between 1500 and 1800 most of the southern Nubians began to adopt Arabic as their first language and increasingly to think of themselves as Arabs. The same trends came gradually also to affect the self-perceptions of other peoples included in the originally multiethnic Funj kingdom.

Nuclear Power

Debate about the use of nuclear technology (and its destructive and constructive capabilities) continues to rage more than sixty years after the United States released a uranium bomb on Hiroshima and (three days later) a plutonium bomb on Nagasaki. As contentious an issue as nuclear weapons remains, proponents of nuclear power champion its ability to produce energy more cleanly than any other resource.

When the first nuclear weapons exploded over Japan in 1945, observers all over the world knew that human life had changed in an instant. In the years since, nuclear technology has struggled to define itself as a public good when the public seemed more inclined to view it as an evil. Its proponents argue that electricity made from nuclear reactors has the capability to power the world more cleanly than any other resource can. Opponents are less sure. As the debate rages, nuclear power has become an increasingly important part of world energy.

Beginning as a Bomb

By the late 1930s World War II threatened the globe. Leaders of every nation searched for any edge that would defeat the enemy forces. Scientists in the United States and Germany experimented with nuclear reactions. In Germany leaders felt that such a technology might be a decisive force in the war effort. In reaction, U.S. scientists enlisted U.S. physicist Albert Einstein to write a letter about their research to President Franklin D. Roosevelt. In his letter Einstein stressed the technology's potential—particularly if

it were developed by the enemy. In October 1939 Roosevelt authorized government funding for atomic research.

Eventually science and the military would be linked in a way never before seen. However, first scientists needed to demonstrate the viability of an atomic reaction. Of course, today the concept of force generated by separating atomic particles is fairly well known; however, in 1940 such a concept smacked of science fiction. In 1940 the U.S. physicists Enrico Fermi and Leo Szilard received a government contract to construct a reactor at Columbia University. Other reactor experiments took place in a laboratory under the west stands of Stagg Field at the University of Chicago. In December 1942 Fermi achieved what the scientists considered the first self-sustained nuclear reaction. It was time to take the reaction out of doors, and this process would greatly increase the scope and scale of the experiment.
